Radars have occasionally detected breaking Kelvin-Helmholtz (KH) waves under clear-air conditions in the atmospheric boundary layer and in the free troposphere. However, very few direct measurements of such waves within clouds have previously been reported and those have not clearly documented wave breaking. In this article, we present some of the most detailed and striking radar observations to date of breaking KH waves within clouds and at cloud top and discuss their relevance to the issue of cloud-top entrainment, which is believed to be important in convective and stratiform clouds. Aircraft observations reported by Stith suggest that vortex-like circulations near cloud top are an entrainment mechanism in cumuliform clouds. Laboratory and modeling studies have examined possibility that KH instability may be responsible for mixing at cloud top, but direct observations have not yet been presented. Preliminary analyses shown here may help fill this gap. The data presented in this paper were obtained during two field projects in 1991 that included observations from the NOAA Wave Propagation Laboratory's K-band Doppler radar (wavelength = 8.7 mm) and special rawinsonde ascents. The sensitivity (-30 dBZ at 10 km range), fine spatial resolution (375-m pulse length and 0.5 degrees beamwidth), velocity measurement precision (5-10 cm s-1), scanning capability, and relative immunity to ground clutter make it sensitive to non-precipitating and weakly precipitating clouds, and make it an excellent instrument to study gravity waves in clouds. In particular, the narrow beam width and short pulse length create scattering volumes that are cylinders 37.5 m long and 45 m (90 m) in diameter at 5 km (10 km) range. These characteristics allow the radar to resolve the detailed structure in breaking KH waves such as have been seen in photographic cloud images.

Rudimentary ground-based K-band radars were once used by the U.S. Air Force to monitor clouds over air bases. The NOAA wave Propagation Laboratory has developed a significantly advanced dual-polarization Doppler K-band system that provides remarkably detailed visualizations of the structure and kinematics of nonprecipitating and weakly precipitating clouds. Unlike lidar and infrared radiometer systems, K-band radar can penetrate liquid water cloud layers and obtain measurements through moderate rainfall and heavy snowfall to reveal intricate cloud features including multiple layers of cloud. This is accomplished at less cost than would be possible with traditional longer wavelength weather radars. The radar's capabilities have been demonstrated in several recent cloud research field projects. In combination with measurements by other remote sensors, the radar can help detect aircraft icing hazards and infer microphysical properties of clouds. An automated, unattended version of the radar could provide a continuous, detailed depiction of the cloud environment in the vicinity of airports. Author (revised)

Satellite cloud retrieval algorithms generally require atmospheric temperature and humidity profiles to determine such cloud properties as pressure and height. For instance, the CO2 slicing technique called the ratio method requires the calculation of theoretical upwelling radiances both at the surface and a prescribed number (40) of atmospheric levels. This technique has been applied to data from, for example, the High Resolution Infrared Radiometer Sounder (HIRS/2, henceforth HIRS) flown aboard the NOAA series of polar orbiting satellites and the High Resolution Interferometer Sounder (HIS). In this particular study, four NOAA-11 HIRS channels in the 15-micron region are used. The ratio method may be applied to various channel combinations to estimate cloud top heights using channels in the 15-mu m region. Presently, the multispectral, multiresolution (MSMR) scheme uses 4 HIRS channel combination estimates for mid- to high-level cloud pressure retrieval and Advanced Very High Resolution Radiometer (AVHRR) data for low-level (is greater than 700 mb) cloud level retrieval. In order to determine theoretical upwelling radiances, atmospheric temperature and water vapor profiles must be provided as well as profiles of other radiatively important gas absorber constituents such as CO2, O3, and CH4. The assumed temperature and humidity profiles have a large effect on transmittance and radiance profiles, which in turn are used with HIRS data to calculate cloud pressure, and thus cloud height and temperature. For large spatial scale satellite data analysis, atmospheric parameterization schemes for cloud retrieval algorithms

are usually based on a gridded product such as that provided by the European Center for Medium Range Weather Forecasting (ECMWF) or the National Meteorological Center (NMC). These global, gridded products prescribe temperature and humidity profiles for a limited number of pressure levels (up to 14) in a vertical atmospheric column. The FIRE IFO 2 experiment provides an opportunity to investigate current atmospheric profile parameterization schemes, compare satellite cloud height results using both gridded products (ECMWF) and high vertical resolution sonde data from the National Weather Service (NWS) and Cross Chain Loran Atmospheric Sounding System (CLASS), and suggest modifications in atmospheric parameterization schemes based on these results. AUTOMATED CLOUD CLASSIFICATION WITH A FUZZY LOGIC EXPERT SYSTEM

Vasanth Tovinkere (Lockheed Engineering and Sciences Co., Hampton, VA.) and Bryan A. Baum *In its* The FIRE Cirrus Science Results 1993 Dec. 1993 p 87-90 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

An unresolved problem in current cloud retrieval algorithms concerns the analysis of scenes containing overlapping cloud layers. Cloud parameterizations are very important both in global climate models and in studies of the Earth's radiation budget. Most cloud retrieval schemes, such as the bispectral method used by the International Satellite Cloud Climatology Project (ISCCP), have no way of determining whether overlapping cloud layers exist in any group of satellite pixels. One promising method uses fuzzy logic to determine whether mixed cloud and/or surface types exist within a group of pixels, such as cirrus, land, and water, or cirrus and stratus. When two or more class types are present, fuzzy logic uses membership values to assign the group of pixels partially to the different class types. The strength of fuzzy logic lies in its ability to work with patterns that may include more than one class, facilitating greater information extraction from satellite radiometric data. The development of the fuzzy logic rule-based expert system involves training the fuzzy classifier with spectral and textural features calculated from accurately labeled 32x32 regions of Advanced Very High Resolution Radiometer (AVHRR) 1.1-km data. The spectral data consists of AVHRR channels 1 (0.55-0.68 mu m), 2 (0.725-1.1 mu m), 3 (3.55-3.93 mu m), 4 (10.5-11.5 mu m), and 5 (11.5-12.5 mu m), which include visible, near-infrared, and infrared window regions. The textural features are based on the gray level difference vector (GLDV) method. A sophisticated new interactive visual image Classification System (IVICS) is used to label samples chosen from scenes collected during the FIRE IFO II. The training samples are chosen from predefined classes, chosen to be ocean, land, unbroken stratiform, broken stratiform, and cirrus. The November 28, 1991 NOAA overpasses contain complex multilevel cloud situations ideal for training and validating the fuzzy logic expert system. Derived from text

METEOROLOGICAL ANALYSIS OF THE DECEMBER 4-6 FIRE CIRRUS-2 CASE

David Starr and Andrew R. Lare (Applied Research Corp., Landover, MD.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 92-97 (For primary document see N94-22292 05-47)

Avail: CASI HC A02/MF A03

During the period 4-6 December 1991, three distinct and separate cirrus cloud systems were observed to move over the FIRE Cirrus-II field site at Coffeyville (COF) in southeastern Kansas. Meteorological analyses of the first and third events are presented here. These cases were well-sampled by the regional rawinsonde network, highly instrumented aircraft, and extensive ground-based remote sensors at COF. Our analyses are primarily based on the rawinsonde observations. Unfortunately, the intervening event was not well-observed by the regional rawinsonde network. Derived from text

Clouds form in moist environments. FIRE Phase II Cirrus Implementation Plan (August, 1990) noted the need for mesoscale measurements of upper tropospheric water vapor content. These measurements are needed for initializing and verifying numerical weather prediction models and for describing the environment in which cirrus clouds develop and dissipate. Various instruments where deployed to measure the water vapor amounts of the upper troposphere during FIRE II (e.g. Raman lidar, CLASS sonds and new cryogenic frost hygrometer on-board aircraft). The formation, maintenance and dissipation of cirrus clouds involve the time variation of the water budget of the upper troposphere. The GOES 6.7 mu m radiance observations are sensitive to the upper tropospheric relative humidity, and therefore proved extremely valuable in planning aircraft missions during the field phase of FIRE II. Warm 6.7 mu m equivalent black body temperatures indicate a relatively dry upper troposphere and were associated with regions generally free of cirrus clouds. Regions that were colder, implying more moisture was available may or may not have had cirrus clouds present. Animation of a time sequence of 6.7 mu m images was particularly useful in planning various FIRE missions. The 6.7 mu m observations can also be very valuable in the verification of model simulations and describing the upper tropospheric synoptic conditions. A quantitative analysis of the 6.7 mu m measurement is required to successfully incorporate these satellite observations into describing the upper tropospheric water vapor budget. Recently, Soden and Bretherton (1993) have proposed a method of deriving an upper tropospheric humidity based on observations from the GOES 6.7 mu m observations. The method is summarized in the next section. In their paper they compare their retrieval method to radiance simulations. Observations were also compared to ECMWF model output to assess the model performance. The FIRE experiment provides a unique opportunity to further verify the GOES upper tropospheric relative humidity retrieval scheme by providing (1) aircraft observations to cross-validate the calibration of the GOES 6.7 mu m channel, (2) accurate upper tropospheric water vapor concentrations for verification, and (3) veritical variability of upper tropospheric water vapor. COMPARISON OF CLOUD BOUNDARIES MEASURED WITH 8.6 mm RADAR AND 10.6 MICROMETER LIDAR

Taneil Uttal and Janet M. Intrieri (Colorado Univ., Boulder.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 107-110 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

One of the most basic cloud properties is location; the height of cloud base and the height of cloud top. The glossary of meteorology defines cloud base (top) as follows: 'For a given cloud or cloud layer, that lowest (highest) level in the atmosphere at which the air contains a perceptible quantity of cloud particles.' Our studies show that for a 8.66 mm radar, and a 10.6 micrometer lidar, the level at which cloud hydrometers become 'perceptible' can vary significantly as a function of the different wavelengths, powers, beamwidths and sampling rates of the two remote sensors. Avail: CASI HC A01/MF A03

To our knowledge, previous observations of cloud boundaries have been limited to studies of cloud bases with ceilometers, cloud tops with satellites, and intermittent reports by aircraft pilots. Comprehensive studies that simultaneously record information of cloud top and cloud base, especially in multiple layer cases, have been difficult, and require the use of active remote sensors with range-gated information. In this study, we examined a 4-week period during which the NOAA Wave Propagation Laboratory (WPL) 8-mm radar and the Pennsylvania State University (PSU) 3-mm radar operated quasi-continuously, side by side. By quasi-continuously, we mean that both radars operated during all periods when cloud was present, during both daytime and nighttime hours. Using this data, we develop a summary of cloud boundaries for the month of November for a single location in the mid-continental United States. Derived from text

Surface radiation measurements and simultaneous ground-based measurements of the atmosphere during the FIRE'91 cirrus field experiment provided an opportunity to identify crucial measurements and parameterization deficiencies in current cloud-radiation models. Comparisons between measured and calculated broadband surface fluxes with only a small data subset already reveal these needs: accurate humidity and aerosol vertical profiles for clear cases, accurate vertical extinction profiles and dimensions for clouds, and understanding of the (solar) scattering properties of cirrus. Avail: CASI HC A01/MF A03

The impact of cirrus clouds on the radiative budget of the earth depends on the microphysics and scattering properties of the clouds. Cirrus clouds have been especially difficult to observe because of their high altitude and complex tenuous structure. Observations by Abakumova et. al. (1991) show that the near infrared wavelengths are more sensitive to the cirrus cloud properties than the shorter ultraviolet wavelengths. Anikin (1991) was able to show that collimated spectral measurements can be used to determine an effective particle size of the cirrus clouds. Anikin (1991) also showed that the effect of scattering through cloud causes the apparent optical depth of a 10 degrees field of view pyrheliometer to be roughly half the actual optical depth. Stackhouse and Stephens (1991) have shown that the existence of small ice crystals do dramatically affect the radiative properties of the cirrus, though observations taken during the 1986 FIRE were not totally explained by their presence. Avail: CASI HC A01/MF A03

The inference of cirrus cloud properties has many important applications including global climate studies, radiation budget determination, remote sensing techniques and oceanic studies from satellites. Data taken at the Parsons Kansas site during the FIRE II project are used for this study. On November 26 there were initially clear sky conditions gradually giving way to a progressively thickening cirrus shield over a period of a few hours. Interferometer radiosonde and lidar data were taken throughout this event. Two techniques are used to infer the downward spectral emittance of the observed cirrus layer. One uses only measurements and the other involves measurements and FASCODE III calculations. FASCODE III is a line-by line radiance/transmittance model developed at the Air Force Geophysics Laboratory. Author

CO2 LIDAR OBSERVATIONS OF MOUNT PINATUBO DEBRIS: FIRE 2 AND LONGER-TERM MEASUREMENTS

David H. Levinson, Madison J. Post (National Oceanic and Atmospheric Administration, Boulder, CO.), and Christian J. Grund (National Oceanic and Atmospheric Administration, Boulder, CO.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 130-133 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

The volcanic debris in the stratosphere from the June 1991 eruption of Mt. Pinatubo first appeared over the NOAA Wave Propagation Laboratory (WPL) field site near Boulder, Colorado (40.15 N, 105.23 W), in July of 1991. The presence of the Pinatubo cloud has allowed us to characterize both the tropospheric and stratospheric aerosol backscatter using the NOAA/WPL CO2 Doppler lidar. The lidar has measured vertical backscatter profiles at lambda = 10.59 mu m for over a decade. Analysis of this dense set of profiles reveals the effects of atmospheric and microphysical processes during the buildup and decay of Mt. Pinatubo's clouds. Further information on the NOAA lidar, specifically calibrations using a hard target, can be found in Post and Cupp (1990). We present results of those measurements for June 15, 1991, through December 31, 1992. During that period of longer-term measurements, WPL took part in FIRE II (First ISCCP (International Satellite Cloud Climatology Project) Regional Experiment II), from November 12 through December 8, 1991, measuring vertical backscatter profiles almost daily. One of the mechanisms for purging stratospheric aerosols is tropopause folding, which occurs in cold-core extratropical cyclones. Tropospheric mass loading occurs during folding events which can substantially increase the amount of ice nuclei in the upper troposphere, and may affect the formation of cirrus in that region. Spring and fall are prominent times for tropopause folding events because of the migration of the subtropical and polar jet streams during the transition seasons. Sassen has suggested that the volcanic aerosols from Pinatubo played a role in the formation of cirrus during FIRE II, particularly during a period of moist subtropical flow on December 5-6, 1991. Avail: CASI HC A01/MF A03

The Penn State/NCAR mesoscale model, as adapted for use at ARC, was used as a testbed for the development and validation of cloud models for use in General Circulation Models (GCM's). This modeling approach also allows us to intercompare the predictions of the various cloud schemes within the same dynamical framework. The use of the PSU/NCAR mesoscale model also allows us to compare our results with FIRE-II (First International Satellite Cloud Climatology Project Regional Experiment) observations, instead of climate statistics. Though a promising approach, our work to date revealed several difficulties. First, the model by design is limited in spatial coverage and is only run for 12 to 48 hours at a time. Hence the quality of the simulation will depend heavily on the initial conditions. The poor quality of upper-tropospheric measurements of water vapor is well known and the situation is particularly bad for mid-latitude winter since the coupling with the surface is less direct than in summer so that relying on the model to spin-up a reasonable moisture field is not always successful. Though one of the most common atmospheric constituents, water vapor is relatively difficult to measure accurately, especially operationally over large areas. The standard NWS sondes have little sensitivity at the low temperatures where cirrus form and the data from the GOES 6.7 micron channel is difficult to quantify. For this reason, the goals of FIRE Cirrus II included characterizing the three-dimensional distribution of water vapor and clouds. In studying the data from FIRE Cirrus II, it was found that no single special observation technique provides accurate regional distributions of water vapor. The Raman lidar provides accurate measurements, but only at the Hub, for levels up to 10 km, and during nighttime hours. The CLASS sondes are more sensitive to moisture at low temperatures than are the NWS sondes, but the four stations only cover an area of two hundred kilometers on a side. The aircraft give the most accurate measurements of water vapor, but are limited in spatial and temporal coverage. This problem is partly alleviated by the use of the MAPS analyses, a four-dimensional data assimilation system that combines the previous 3-hour forecast with the available observations, but its upper-level moisture analyses are sometimes deficient because of the vapor measurement problem. An attempt was made to create a consistent four-dimensional description of the water vapor distribution during the second IFO by subjectively combining data from a variety of sources, including MAPS analyses, CLASS sondes, SPECTRE sondes, NWS sondes, GOES satellite analyses, radars, lidars, and microwave radiometers. Recently, Sassen provided evidence for supercooled water droplets in cirrus uncinus cell heads at temperatures between 40 and -50 C. Chemistry related to volcanic aerosol of stratospheric origin was evoked as an explanation for this phenomenon. Sassen speculated that injections of sulfuric acid droplets into the upper troposphere were accomplished by tropopause folds associated with subtropical jet streams. He also postulated global climatic perturbations due to the effect of these cirrus microphysical perturbations on radiative fluxes. Using data processing and objective analysis techniques described by Mace and Ackerman, the synoptic scale environment was examined for evidence of tropopause folds that may have served as a source mechanism of stratospheric aerosol in the upper troposphere. In presenting an overview of the cirrus clouds comprehensively studied by ground-based and airborne sensors from Coffeyville, KS, during the 5-6 Dec. 1992 Project FIRE (First International Satellite Cloud Climatology Project Regional Experiment) IFO II case study period, evidence is provided that volcanic aerosols from the June 1991 Pinatubo eruptions significantly influenced the formation and maintenance of the cirrus. Following the local appearance of a spur of stratospheric volcanic debris from the subtropics, a series of jet streaks subsequently conditioned the troposphere through tropopause foldings with sulfur-based particles that became effective cirrus cloud-forming nuclei. Aerosol and ozone measurements suggest a complicated history of stratospheric-tropospheric exchanges embedded within the upper level flow, and cirrus cloud formation was noted to occur locally at the boundaries of stratospheric aerosol-enriched layers that became humidified through diffusion, precipitation, or advective processes. Apparent cirrus cloud alterations include abnormally high ice crystal concentrations (up to approximately 600 !(sup -1), small but complex radial ice crystal types, and relatively large haze particles in cirrus uncinus cell heads at temperatures between -40 to -50 C. Implications for volcanic-cirrus cloud climate effects, and usual (non-volcanic aerosol) jet stream cirrus cloud formation are discussed. Author (revised)

THREE DIMENSIONAL MODELING OF CIRRUS DURING THE 1991 FIRE IFO 2: DETAILED PROCESS STUDY Abstract Only
Eric J. Jensen, Owen B. Toon, and Douglas L. Westphal *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 143 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

A three-dimensional model of cirrus cloud formation and evolution, including microphysical, dynamical, and radiative processes, was used to simulate cirrus observed in the FIRE Phase 2 Cirrus field program (13 Nov. - 7 Dec. 1991). Sulfate aerosols, solution drops, ice crystals, and water vapor are all treated as interactive elements in the model. Ice crystal size distributions are fully resolved based on calculations of homogeneous freezing of solution drops, growth by water vapor deposition, evaporation, aggregation, and vertical transport. Visible and infrared radiative fluxes, and radiative heating rates are calculated using the two-stream algorithm described by Toon et al. Wind velocities, diffusion coefficients, and temperatures were taken from the MAPS analyses and the MM4 mesoscale model simulations. Within the model, moisture is transported and converted to liquid or vapor by the microphysical processes. The simulated cloud bulk and microphysical properties are shown in detail for the Nov. 26 and Dec. 5 case studies. Comparisons with lidar, radar, and in situ data are used to determine how well the simulations reproduced the observed cirrus. The roles played by various processes in the model are described in detail. The potential modes of nucleation are evaluated, and the importance of small-scale variations in temperature and humidity are discussed. The importance of competing ice crystal growth mechanisms (water vapor deposition and aggregation) are evaluated based on model simulations. Finally, the importance of ice crystal shape for crystal growth and vertical transport of ice are discussed. Author (revised)

METEOROLOGICAL ANALYSIS OF THE NOVEMBER 25 FIRE CIRRUS-2 CASE: A WELL-DEFINED RIDGE-CREST CIRRUS SYSTEM OVER OKLAHOMA
David Starr and Andrew R. Lare (Applied Research Corp., Landover, MD.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 144-147 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

On the morning of 25 Nov. 1991, a cirrus cloud system formed in a region extending eastward from the continental divide into central Oklahoma

and southwestern Kansas. The system moved slowly eastward during the day and maintained a relatively constant scale and shape. From the satellite perspective, this cloud system had a number of morphological similarities to the 27-28 Oct. FIRE (First International Satellite Cloud Climatology Project Regional Experiment) Cirrus-1 case analyzed by Starr and Wylie. By comparison, the present case had much better rawinsonde coverage. The rawinsonde network was much more extensive and the cloud system was relatively slow moving and well-located with respect to the enhanced sounding network and the National Weather Service (NWS) Wind Profiler Network. In addition to the rawinsonde soundings (1200 and 1800 UTC on 25 Nov. and 0000 and 0600 UTC on 26 Nov.) and satellite observations, four aircraft sorties were flown in the northern portion of this cirrus cloud system from mid-morning to mid afternoon. These included microphysical-radiation profiling missions by the NCAR Sabreliner near Tulsa (about midway between COF and OUN) and the NCAR King Air near Ponca City (about 80 km upwind of Tulsa), a microphysical profiling mission by the UND Citation near Tulsa, and a NASA ER-2 overflight. Thus, very good data are available for this case although, unfortunately, the cloud system remained south of the FIRE Hub site at Coffeyville (COF) where extensive ground-based remote sensor was located. The northern edge of the cloud system was visible from COF during most of the day. Given the wealth of available in situ and remote sensing observations, the similarity to the FIRE Cirrus-1 focal case study, and the particularly good match in scale and location of the cloud system with the rawinsonde and profiler networks, analysis of this case may yield very useful results on the life-cycle of this cirrus cloud system. The quality of the meteorological description for this case was assessed based on our preliminary analysis of the rawinsonde observations. Author (revised)

CIRRUS CLOUD DEVELOPMENT IN A MOBILE UPPER TROPOSPHERIC TROUGH: THE NOVEMBER 26TH FIRE CIRRUS CASE STUDY

Gerald G. Mace and Thomas P. Ackerman *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 148-152 (For primary document see N94-22292 05-47)

(Contract NAG1-1095; NAG1-999; DE-FG02-90ER-61071)

Avail: CASI HC A01/MF A03

The period from 18 UTC 26 Nov. 1991 to roughly 23 UTC 26 Nov. 1991 is one of the study periods of the FIRE (First International Satellite Cloud Climatology Regional Experiment) 2 field campaign. The middle and upper tropospheric cloud data that was collected during this time allowed FIRE scientists to learn a great deal about the detailed structure, microphysics, and radiative characteristics of the mid latitude cirrus that occurred during that time. Modeling studies that range from the microphysical to the mesoscale are now underway attempting to piece the detailed knowledge of this cloud system into a coherent picture of the atmospheric processes important to cirrus cloud development and maintenance. An important component of the modeling work, either as an input parameter in the case of cloud-scale models, or as output in the case of meso and larger scale models, is the large scale forcing of the cloud system. By forcing we mean the synoptic scale vertical motions and moisture budget that initially send air parcels ascending and supply the water vapor to allow condensation during ascent. Defining this forcing from the synoptic scale to the cloud scale is one of the stated scientific objectives of the FIRE program. From the standpoint of model validation, it is also necessary that the vertical motions and large scale moisture budget of the case studies be derived from observations. It is considered important that the models used to simulate the observed cloud fields begin with the correct dynamics and that the dynamics be in the right place for the right reasons. Avail: CASI HC A01/MF A03

Cirrus clouds play an important role in the climate and general circulation because they significantly modulate the radiation properties of the atmosphere. However understanding the processes that govern their presence is made difficult by their high altitude, variable thickness, complex microphysical structure, and relatively little knowledge of the vertical motion field. In the FIRE 2 (First International Satellite Cloud Climatology Regional Experiment) experiment, a 404 MHz wind profiler was set up to provide continuous measurements of clear air wind field at Parsons, Kansas. Simultaneously, the NOAA wind profiler network supplied a wider spacial scale observation. On 26 Nov. 1991, the most significant cirrus cloud phenomena during the experiment with a jet streak at 250 Mb occurred. Analyses of the vertical wind velocity are made by utilizing different methods based on wind profiler data, among them the direct measurements from CSU wind profiler and NOAA network wind profilers, VAD (Velocity Azimuth Display) technique and the kinematic method. MESOSCALE SIMULATIONS OF THE NOVEMBER 25-26 AND DECEMBER 5-6 CIRRUS CASES USING THE RAMS MODEL

J. L. Harrington, Michael P. Meyers, and William R. Cotton *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 158-161 (For primary document see N94-22292 05-47)

(Grants AF-AFOSR-0296-91)

Avail: CASI HC A01/MF A03

The Regional Atmospheric Modeling System (RAMS), developed at Colorado State University, was used during the First ISCCP (International Satellite Cloud Climatology Project) Regional Experiment (FIRE) 2 (13 Nov. through 6 Dec. 1991) to provide real time forecasts of cirrus clouds. Forecasts were run once a day, initializing with the 0000 UTC dataset provided by NOAA (Forecast Systems Laboratory (FSL) Mesoscale Analysis and Prediction System (MAPS)). In order to obtain better agreement with observations, a second set of simulations were done for the FIRE 2 cases that occurred on 25-26 Nov. and 5-6 Dec. In this set of simulations, a more complex radiation scheme was used, the Chen/Cotton radiation scheme, along with the nucleation of ice occurring at ice supersaturations as opposed to nucleation occurring at water supersaturations that was done in the actual forecast version. The runs using these more complex schemes took longer wall clock time (7-9 hours for the actual forecasts as compared to 12-14 hrs for the runs using the more complex schemes) however, the final results of the simulations were definitely improved upon. Comparisons between these two sets of simulations are given. Now underway are simulations of these cases using a closed analytical solution for the auto-conversion of ice from a pristine ice class (sizes less than about 50 microns in effective diameter) to a snow class (effective diameters on the order of several hundred microns). This solution is employed along with a new scheme for the nucleation of ice crystals due to Meyers et al and Demott et al. The scheme is derived assuming complete gamma distributions for both the pristine and snow classes. The time rate of change of the number concentration and mass mixing-ratio of each distribution is found by calculating either the flux of crystals that grow beyond a certain critical diameter by vapor deposition in an ice supersaturated regime or by calculating the flux of crystals that evaporate to sizes below that same critical effective diameter. DYNAMICAL CHARACTERISTICS OF CIRRUS CLOUDS FROM AIRCRAFT AND RADAR MEASUREMENTS

I. Gultepe, David Starr, A. J. Heymsfield (National Center for Atmospheric Research, Boulder, CO.), M. Poellot (North Dakota Univ., Grand Forks.), T. Uttal (National Oceanic and Atmospheric Administration, Boulder, CO.), and T. Ackerman (Pennsylvania State Univ., University Park.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 162-165 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

Cirrus clouds play an important role in climate and in the development of other types of clouds. Although there are many studies of clouds within the boundary layer, cirrus clouds have been neglected up until the last decade. New tools and in-situ measurements of various physical and dynamical parameters permit us to now study cirrus clouds in much greater detail. Physical and dynamical structures of cirrus clouds were studied in

detail by Heymsfield using aircraft measurements. He emphasized the importance of interactions among physical and dynamical processes. Cirrus clouds often exhibit complex physical and dynamical structure. Upper tropospheric flows contain not only coherent structures, but also chaotic movements. The coherent structures (organized movements) transfer significant amounts of heat and momentum while their form, size, and intensity depend strongly on environmental instability. Various dynamical structures including cells, waves, and turbulence are studied in order to understand cirrus cloud formation and development. Author (revised)

ESTIMATION OF CIRRUS CLOUD PARTICLE FALLSPEEDS FROM VERTICALLY POINTING DOPPLER RADAR

Brad W. Orr and Robert A. Kropfli *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 166-168 Sponsored in part by NOAA (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

The First ISCCP (International Satellite Cloud Climatology Project) Regional Experiment 2 (FIRE 2) was conducted in Coffeyville, Kansas in late 1991 to study the microphysical and radiative properties of cirrus clouds. A variety of active and passive remote sensors were employed, including an 8-mm-wavelength cloud-sensing Doppler radar developed at the Wave Propagation Laboratory (WPL). The radar, having excellent sensitivity to cloud particles (-30 dBZ at 10 km), good spatial resolution (37 m), and velocity precision (.05 ms -1), is an excellent tool for observing cirrus clouds. Having this radar directed toward the zenith for long periods of time during FIRE 2 permitted the reflectivity-weighted particle fallspeed to be related to reflectivity which allowed a separation of ice particle fallspeeds from vertical air motions. Additionally, such relationships proved useful in other multi-sensor techniques for determining vertical profiles of ice particle characteristic size and ice water content in cirrus clouds. The analysis method and the results of applying it to cirrus cloud reflectivity and velocity data collected during FIRE 2 are discussed. Author (revised)

NORMALIZED VERTICAL ICE MASS FLUX PROFILES FROM VERTICALLY POINTING 8-mm-WAVELENGTH DOPPLER RADAR

Brad W. Orr and Robert A. Kropfli *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 169-172 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

During the FIRE 2 (First International Satellite Cloud Climatology Project Regional Experiment) project, NOAA's Wave Propagation Laboratory (WPL) operated its 8-mm wavelength Doppler radar extensively in the vertically pointing mode. This allowed for the calculation of a number of important cirrus cloud parameters, including cloud boundary statistics, cloud particle characteristic sizes and concentrations, and ice mass content (imc). The flux of imc, or, alternatively, ice mass flux (imf), is also an important parameter of a cirrus cloud system. Ice mass flux is important in the vertical redistribution of water substance and thus, in part, determines the cloud evolution. It is important for the development of cloud parameterizations to be able to define the essential physical characteristics of large populations of clouds in the simplest possible way. One method would be to normalize profiles of observed cloud properties, such as those mentioned above, in ways similar to those used in the convective boundary layer. The height then scales from 0.0 at cloud base to 1.0 at cloud top, and the measured cloud parameter scales by its maximum value so that all normalized profiles have 1.0 as their maximum value. The goal is that there will be a 'universal' shape to profiles of the normalized data. This idea was applied to estimates of imf calculated from data obtained by the WPL cloud radar during FIRE II. Other quantities such as median particle diameter, concentration, and ice mass content can also be estimated with this radar, and we expect to also examine normalized profiles of these quantities in time for the 1993 FIRE II meeting. A COMPARISON OF SMALL AND LARGER MESOSCALE LATENT HEAT AND RADIATIVE FLUXES: DECEMBER 6 CASE STUDY

I. Gultepe, David Starr, and A. J. Heymsfield (National Center for Atmospheric Research, Boulder, CO.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 173-176 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

Because of the small amounts of water vapor, the potential for rapid changes, and the very cold temperatures in the upper troposphere, moisture measuring instruments face several problems related to calibration and response. Calculations of eddy moisture fluxes are, therefore, subject to significant uncertainty. The purpose of this study is to examine the importance of latent heat (moisture) fluxes due to small and larger mesoscale circulations in comparison to radiative fluxes within cirrus. Scale separation is made at about 1 km because of significant changes in the structures within cirrus. Only observations at warmer than -40 C are used in this study. The EG&G hygrometer that is used for measuring dewpoint temperature (Td) is believed to be fairly accurate down to -40 C. On the other hand, Lyman-Alpha (L-alpha) hygrometer measurements of moisture may include large drift errors. In order to compensate for these drift errors, the L-alpha hygrometer is often calibrated against the EG&G hygrometer. However, large errors ensue for Td measurements at temperatures less than -40 C. The cryogenic hygrometer frost point measurements may be used to calibrate L-alpha measurements at temperatures less than -40 C. In this study, however, measurements obtained by EG&G hygrometer and L-alpha measurements are used for the flux calculations. Derived from text

IMPORTANCE OF AGGREGATION AND SMALL ICE CRYSTALS IN CIRRUS CLOUDS, BASED ON OBSERVATIONS AND AN ICE PARTICLE GROWTH MODEL

David L. Mitchell, Steven K. Chai, Yayi Dong, W. Patrick Arnott, and John Hallett *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 177-180 (For primary document see N94-22292 05-47)
(Grants NAG1-1113; NA16RC0118-01)
Avail: CASI HC A01/MF A03

The 1 November 1986 FIRE I case study was used to test an ice particle growth model which predicts bimodal size spectra in cirrus clouds. The model was developed from an analytically based model which predicts the height evolution of monomodal ice particle size spectra from the measured ice water content (IWC). Size spectra from the monomodal model are represented by a gamma distribution, N(D) = N(sub o)D(exp nu)exp(-lambda D), where D = ice particle maximum dimension. The slope parameter, lambda, and the parameter N(sub o) are predicted from the IWC through the growth processes of vapor diffusion and aggregation. The model formulation is analytical, computationally efficient, and well suited for incorporation into larger models. The monomodal model has been validated against two other cirrus cloud case studies. From the monomodal size spectra, the size distributions which determine concentrations of ice particles less than about 150 mu m are predicted. Derived from text

CALIBRATION OF RADIATION CODES IN CLIMATE MODELS: COMPARISON OF CALCULATIONS WITH OBSERVATIONS FROM THE SPECTRAL RADIATION EXPERIMENT (SPECTRE)

R. G. Ellingson, W. J. Wiscombe, J. DeLuisi, H. Melfi, and W. Smith *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 181-184 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

The primary goal of SPECTRE is to: close the loopholes by which longwave radiation models have eluded incisive comparisons with measurements. Likewise, the experimental approach was quite simple in concept, namely: accurately measure the zenith infrared radiance at high spectral resolution while simultaneously profiling the radiatively important atmospheric properties with conventional and remote sensing devices. The field phase of SPECTRE was carried out as part of FIRE Cirrus II, and detailed spectra of the down welling radiance were obtained by several interferometers simultaneous to the measurement of the optical properties of the atmosphere. We are now well along in the process of analyzing the data and calibrating radiation codes so that they may be used more effectively in climate related studies. The calibration is being done with models ranging from the most detailed (line-by-line) to the broad-band parameterizations used in climate models. This paper summarizes our

progress in the calibration for clear-sky conditions. When this stage is completed, we will move on to the calibration for cirrus conditions.

Avail: CASI HC A01/MF A03

In November of 1991, the First ISCCP (International Satellite Cloud Climatology Project) Regional Experiment (FIRE) Phase II cirrus study took place at Coffeyville, Kansas. The field experiment incorporated instrumentation from surface, aircraft, and satellite to attempt to define the optical, radiative, and microphysical characteristics of these high altitude, predominantly ice clouds. The NCAR King Air research aircraft was outfitted with a variety of radiative and microphysical instrumentation for the FIRE II project. Included for this project was the SSH-2, a 16-channel passive radiometer. The SSH-2 was originally designed as a space-qualified infrared (IR) temperature and water vapor sounder for deployment onboard the Defense Meteorological Satellite Program (DMSP) series of environmental satellites. For this experiment, only those channels associated with the water vapor profiling function have been examined although downwelling radiance measurements were taken at all channels during the project. With supporting information from the aircraft telemetry observations it may be possible to relate these SSH-2 measurements to cloud radiative and microphysical properties. The following sections will describe the spectral characteristics of the instrument, the calibration scheme used to convert the raw measured counts into calibrated radiances, and the case studies that will be covered in this paper. This will be followed by a discussion of the results of this preliminary investigation and a description of future work to be done.

INVESTIGATION OF THE EFFECTS OF THE MACROPHYSICAL AND MICROPHYSICAL PROPERTIES OF CIRRUS CLOUDS ON THE RETRIEVAL OF OPTICAL PROPERTIES: RESULTS FOR FIRE 2

Paul W. Stackhouse, Jr. and Graeme L. Stephens *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 189-192 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

Due to the prevalence and persistence of cirrus cloudiness across the globe, cirrus clouds are believed to have an important effect on the climate. Stephens et al., (1990) among others have shown that the important factor determining how cirrus clouds modulate the climate is the balance between the albedo and emittance effect of the cloud systems. This factor was shown to depend in part upon the effective sizes of the cirrus cloud particles. Since effective sizes of cirrus cloud microphysical distributions are used as a basis of parameterizations in climate models, it is crucial that the relationships between effective sizes and radiative properties be clearly established. In this preliminary study, the retrieval of cirrus cloud effective sizes are examined using a two dimensional radiative transfer model for a cirrus cloud case sampled during FIRE Cirrus 11. The purpose of this paper is to present preliminary results from the SHSG model demonstrating the sensitivity of the bispectral relationships of reflected radiances and thus the retrieval of effective sizes to phase function and dimensionality.

Avail: CASI HC A01/MF A03

One of the most commonly noted uncertainties with respect to the modeling of cirrus clouds and their effect upon the planetary radiation balance is the disputed validity of the use of Mie scattering results as an approximation to the scattering results of the hexagonal plates and columns found in cirrus clouds. This approximation has historically been a kind of default, a result of the lack of an appropriate analytical solution of Maxwell's equations to particles other than infinite cylinders and spheroids. Recently, however, the use of such approximate techniques as the Discrete Dipole Approximation has made scattering solutions on such particles a computationally intensive but feasible possibility. In this study, the Discrete Dipole Approximation (DDA) developed by Flatau (1992) is used to find such solutions for homogeneous, circular cylinders and disks. This can serve to not only assess the validity of the current radiative transfer schemes which are available for the study of cirrus but also to extend the current approximation of equivalent spheres to an approximation of second order, homogeneous finite circular cylinders and disks. The results will be presented in the form of a single variable, the extinction efficiency.

SURFACE-INDUCED BRIGHTNESS TEMPERATURE VARIATIONS AND THEIR EFFECTS ON DETECTING THIN CIRRUS CLOUDS USING IR EMISSION CHANNELS IN THE 8-12 MICROMETER REGION

Bo-Cai Gao and W. J. Wiscombe *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 197-200 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

A method for detecting cirrus clouds in terms of brightness temperature differences between narrow bands at 8, 11, and 12 mu m has been proposed by Ackerman et al. (1990). In this method, the variation of emissivity with wavelength for different surface targets was not taken into consideration. Based on state-of-the-art laboratory measurements of reflectance spectra of terrestrial materials by Salisbury and D'Aria (1992), we have found that the brightness temperature differences between the 8 and 11 mu m bands for soils, rocks and minerals, and dry vegetation can vary between approximately -8 K and +8 K due solely to surface emissivity variations. We conclude that although the method of Ackerman et al. is useful for detecting cirrus clouds over areas covered by green vegetation, water, and ice, it is less effective for detecting cirrus clouds over areas covered by bare soils, rocks and minerals, and dry vegetation. In addition, we recommend that in future the variation of surface emissivity with wavelength should be taken into account in algorithms for retrieving surface temperatures and low-level atmospheric temperature and water vapor profiles.

REMOTE SENSING ESTIMATES OF CIRRUS PARTICLE SIZE FOR TROPICAL AND MIDLATITUDE CIRRUS: HEXAGONAL CRYSTALS AND ICE SPHERES

Bruce A. Wielicki, Patrick Minnis, Robert Arduini (Lockheed Engineering and Sciences Co., Hampton, VA.), Lindsay Parker (Lockheed Engineering and Sciences Co., Hampton, VA.), Si-Chee Tsay (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.), Yoshihide Takano (Utah Univ., Salt Lake City.), and Kuo-Nan Liou (Utah Univ., Salt Lake City.) *In its* The FIRE Cirrus Science Results 1993 Dec. 1993 p 201-204 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

A large discrepancy exists in current estimates of a mean cirrus particle size appropriate for calculations of the effects of these ice clouds on solar and thermal infrared radiative fluxes. For spheres with large size parameter (x = (2 pi r / lambda) is greater than 30, where r is particle radius), and moderate absorption (n(sup i) x less than 1, where n(sup i) is imaginary index of refraction for ice), the optimal effective particle radius is given by: r(sub e) = integral of r(exp 3)n(r)dr / integral of r(exp 2)n(r)dr. For the remote sensing of cirrus particle size at wavelengths of 0.83, 1.65, and 2.21 mu m, a 50 mu m ice sphere would have a size parameter of about 200, and values of n(sup i) x of 0, 0.045, and 0.06, satisfying the above conditions. However, while r(sub e) is a well-defined parameter for spheres, this cross-section area-weighted particle radius can only be extended to non-spherical particles by defining some equivalent sphere, typically an equivalent volume or equivalent cross-section area sphere.

Using equivalent volume spheres, values of r(sub e) obtained over Lake Michigan on October 28, 1986, during FIRE phase I varied from 200 mu m (King Air 2D Imaging probes) to 60 mu m (Landsat reflectances at 0.83, 1.65, and 2.2 mu m), to 25 mu m (HIS spectrometer thermal emission between 8 and 12 mu m). Three major uncertainties were identified in this comparison: small ice particles missed by the 2D-C aircraft probes, uncertain ice refractive index, and uncertainties in the single scatter albedos and scattering phase functions used in the radiative calculations. Since the first FIRE cirrus results, advances have been made in all three areas. The present paper reports on improvements in the radiative modeling of ice particles at 0.83, 1.65, and 2.21 mu m wavelengths appropriate for comparisons to Landsat Thematic Mapper data. The paper also includes new results for Landsat observations of ice clouds in the eastern and western tropical Pacific. Derived from text

Because the volumetric census of deep and bottom water in the North Atlantic Ocean consists of three isolated linear ridges along which heat and salt flow through the main volumetric mode (and point of intersections), it is possible to deduce the expected ratio of heat flux and ratio of salt fluxes measured in the Denmark Strait overflow off Greenland and in the Antarctic Bottom Water near the equator. The weakly stratified layers of North Atlantic Deep Water fall on the nearly linear ridge at temperatures above that of the mode. There is an incompatibility between observed ratio and deduced ratio. It is predicted that a remeasurement of the flux of Antarctic Bottom Water near the equator will show that the previous determination of 4 deg N is unrepresentatively low. DTIC

Data on underwater visibility in tropical Australian waters, in the form of Secchi disc depths and light attenuation coefficients were collected and are presented in the form of maps with Secchi depths grouped in the ranges: less than 5 m, 5 m to 10 m, and greater than 10 m. As one would expect there is a general trend for water turbidity to decrease (or Secchi depth to increase) with depth, and for turbidity to be high in areas with a large tidal range. It can be seen, from the maps, that high turbidity would not infrequently limit diver and remotely operated vehicle operations along Australia's northern coastal shipping routes and in major port approaches. Interest in making use of the existence of Fraunhofer lines to reduce

solar background noise for the Satellite Laser Communications (SLC) program prompted the requirement for making underwater in situ characterizations of five Fraunhofer lines in the blue-green spectrum. Recent papers that discuss and attempt to explain frequent occurrences of high measured values for underwater irradiance raised concerns about the persistence of Fraunhofer lines. The effect of an increased light field could significantly reduce (potentially eliminate) the absorption depth of Fraunhofer lines and reduce their solar-rejection benefits to optical communications. These characterizations were made from a surface ship off the coast of Hawaii in Aug. 1989. Fraunhofer lines at 420, 440, 486, 518, and 532 nm were characterized at the surface and at four discrete depths to a maximum depth of 90 m. These are the first known characterizations of Fraunhofer lines underwater. A high resolution scan from 450 to 550 nm was also made at a depth of 73 m. The results from this experiment showed no differences between the surface and underwater scans suggesting the effects of interwavelength scattering is less than originally proposed. DTIC

SIMBAT THEORETICAL MANUAL Final Report, Oct. 1986 - Sep. 1990
Leon E. Borgman, Warren A. Bartel, and David R. Shields Aug. 1993 81 p
(AD-A271063; NCEL-TR-941) Avail: CASI HC A05/MF A01

This manual develops the theory of the Conditional Ocean Wave Simulation Model (SIMBAT). SIMBAT is a high performance FORTRAN F77 based computer model that uses the Fast Fourier Transform (FFT) to produce ocean wave properties for ocean engineering applications. The model assumes the wave properties form a Gaussian stochastic process. SIMBAT may be used to perform a conditional or unconditional simulation. A conditional simulation uses a measured or existing input time series and forces the simulated wave properties to adhere to the input time series but also follow the laws of multivariate normal probability. An unconditional simulation uses a measured or created ocean wave spectra to randomly simulate the ocean wave properties. The program features include the following: creation of directional ocean wave spectra, water particle kinematic stretching, conditioning time series using an input time series less than or equal to the simulation length, use of Legendre orthogonal polynomials for post-creation of wave properties by program CKPOLY, and error checking. INVERSION OF GRAVITY AND BATHYMETRY IN OCEANIC REGIONS FOR LONG-WAVELENGTH VARIATIONS IN UPPER MANTLE TEMPERATURE AND COMPOSITION Final Report, 1 Jan. 1992 - 30 Jun. 1993
Sean C. Solomon and Thomas H. Jordan 17 Sep. 1993 5 p
(Grant NAGw-3036)
(NASA-CR-192272; NAS 1.26:192272) Avail: CASI HC A01/MF A01

Long-wavelength variations in geoid height, bathymetry, and SS-S travel times are all relatable to lateral variations in the characteristic temperature and bulk composition of the upper mantle. The temperature and composition are in turn relatable to mantle convection and the degree of melt extraction from the upper mantle residuum. Thus the combined inversion of the geoid or gravity field, residual bathymetry, and seismic velocity information offers the promise of resolving fundamental aspects of the pattern of mantle dynamics. The use of differential body wave travel times as a measure of seismic velocity information, in particular, permits resolution of lateral variations at scales not resolvable by conventional global or regional-scale seismic tomography with long-period surface waves. These intermediate scale lengths, well resolved in global gravity field models, are crucial for understanding the details of any chemical or physical layering in the mantle and of the characteristics of so-called 'small-scale' convection beneath oceanic lithosphere. In 1991 a three-year project to the NASA Geophysics Program was proposed to carry out a systematic inversion of long-wavelength geoid anomalies, residual bathymetric anomalies, and differential SS-S travel time delays for the lateral variation in characteristic temperature and bulk composition of the oceanic upper mantle. The project was funded as a three-year award, beginning on 1 Jan. 1992. Author

USE OF MICROWAVE POLARIMETRY TO ENHANCE SAR IMAGES OF THE OCEAN SURFACE Final Report
Robert E. McIntosh Sep. 1993 5 p
(Contract N00014-89-J-3230)
(AD-A271911) Avail: CASI HC A01/MF A01

The goal is to investigate the coherent backscatter of microwave signals from the ocean surface to better understand the effects of surface motion on synthetic aperture radar images. The objective is to analyze the behavior of coherent electromagnetic backscatter from the ocean surface for a dual frequency dual polarization radar. Frequency and polarization diversity provides a picture of the mechanisms involved in the microwave backscatter. In this study data were obtained from various UMass radar systems to obtain extensive radar observations of the ocean surface at the FPN research tower, in the North Sea, Germany. Some of the results were reported in the publications listed at the end of this report. DTIC

SHIPBOARD ADCP OBSERVATIONS DURING RRS CHARLES DARWIN CRUISE 62
M. C. Hartman 1992 25 p
(IOS-298-1992; ETN-93-94561) Avail: CASI HC A03/MF A01

Shipboard Acoustic Doppler Current Profiler (ADCP) observations made during Aug. 1991 when RRS Charles Darwin Cruise 62 occupied Conductivity/Temperature/Depth (CTD) stations in a World Ocean Circulation Experiment (WOCE) control volume in the north Atlantic are reported. The 150 kHz ADCP was operating throughout producing data on water velocity and echo amplitude while the ship was under way and on station. A description of the set up and data processing route used is provided. A summary of the current velocity data collected from the instrument while on station is given as contour plots for each leg of the cruise. ESA

FOUR-DIMENSIONAL REMOTE SENSING OF THE MARINE BOUNDARY LAYER WITH A DIGITAL BEAMFORMING RADAR WIND PROFILER Final Report, 1 Apr. - 30 Sep. 1993
James B. Mead 30 Sep. 1993 32 p
(Contract N00014-93-C-0042)
(AD-A270627) Avail: CASI HC A03/MF A01

Research performed by Quadrant Engineering is detailed. The purpose was to determine the feasibility of deploying a shipboard turbulent eddy profiling (TEP) radar system for studying the dynamics of the marine boundary layer. A similar system is currently being developed by the University of Massachusetts to study the atmospheric boundary over land. During the phase 1 study, Quadrant Engineering reviewed the design of the land based system, and determined that a slightly scaled down version of that system would be suitable for deployment on a large research vessel, such as the Knorr, operated by Woods Hole Oceanographic Institute. A design for the shipboard TEP system is presented and the particular requirements of installation on the Knorr are considered. The application of TEP to boundary layer research, especially in terms of complementing Large Eddy Simulation (LES) models, is also described. DTIC

(Contract N00014-89-J-1021)
(AD-A272001) Avail: CASI HC A01/MF A01

Our goal is to better understand the system that produces the oceanic crust. Because the seafloor is a product of this system we believe that fundamental insight can be gained through the study of seafloor topography and the spatial variation in its characteristics. Our project has focused on applying and further developing our techniques for analyzing seafloor topography and combining our techniques for seafloor characterization with other data sources (e.g., seismicity) and models. A SURVEY OF THE IMPACT ON ACOUSTIC PROPAGATION OF WARM CORE OCEAN EDDYS Final Report
David G. Browning, Joseph M. Monti, and Linda S. Petitpas 21 Sep. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272188; NUSW-NPT-TD-10451) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Warm core eddys have been found throughout the oceans of the world. Most have a bowl-like shape extending down from the surface, which, along with an increased sound speed due to the warmer water core, causes more acoustic energy to be refracted toward the surface than would occur without an eddy present. However, the impact on acoustic propagation varies significantly from ocean to ocean, because of variations in eddy size and core temperature, as well as sound speed profile differences in the adjoining waters. Examples are given from the North and South Atlantic Oceans, North and South Pacific Oceans, Greenland and Norwegian Seas. DTIC

ESTIMATING THE ROTATION RATE OF MESOSCALE OCEAN RINGS FROM SATELLITE ALTIMETRY Final Report
Theodore J. Bennett, Jr. 26 Oct. 1993 18 p
(AF Proj. 2008)
(AD-A272922; NRL/FR/7322-93-9443) Avail: CASI HC A03/MF A01

The mesoscale ocean environment has considerable impact on underwater acoustics. However, the ocean is such a data-sparse environment, especially at depth, that it is difficult to make effective ocean nowcasts and forecasts of the environment. A key input to nowcasts and forecasts is the rotation rate of mesoscale ocean rings. This report presents a technique for determining the rotation rate from satellite altimetry. The technique offers the prospect of a cost-effective system for monitoring this key ocean parameter. DTIC

AIRBORNE SURFACE BACKSCATTERING STRENGTH MEASUREMENTS IN THE WESTERN ATLANTIC OCEAN Final Report
John P. Crockett, Peter M. Ogden, and Fred T. Erskine 17 Sep. 1993 38 p
(NR Proj. R03-5-B-03)
(AD-A271737; NRL/FR/7142-93-9563) Avail: CASI HC A03/MF A01

This report presents the results from a series of airborne, SUS-based acoustic surface backscattering strength tests conducted over the western Atlantic Ocean during April 1988. We describe the airborne technique used to gather the acoustic data and the environmental data (sound speed profiles and wind speed). Analysis provides information on sea surface acoustic backscattering strengths for mean grazing angles from 7 deg to 30 deg, wind speeds from 7 to 18 m/s, and frequencies from 50 to 800 Hz. The data analysis procedure is outlined, and the results are compared to first-order perturbation theory (air-water interface scatter), the Chapman-Harris empirical formula, and the Ogden-Erskine empirical algorithm. The absolute error in measured scattering strengths is approximately + or - 5 dB. The data comparison emphasizes the use of wind history as an environmental predictor of surface scattering. The results are summarized, and a list of the lessons learned concerning the experimental technique is provided. Brief analyses of the sound speed profiles and wind speed data are appended. DTIC

COMPARISON OF SATELLITE-DERIVED VELOCITY FIELDS IN THE COASTAL TRANSITION ZONE Final Report
26 Oct. 1993 3 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1808)
(AD-A272565) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Two methods of estimating surface velocity vectors from advanced very high resolution radiometer (AVHRR) data were applied to the same set of images and the results were compared with in situ and altimeter measurements. The first method used an automated feature-tracking algorithm and the second method used an inversion of the heat equation. The 11 images were from 3 days in July 1988 during the Coastal Transition field program and the in situ data included acoustic Doppler current profiler (ADCP) vectors and velocities from near-surface drifters. The two methods were comparable in their degree of agreement with the in situ data, yielding velocity magnitudes that were 30 - 50% less than drifter and ADCP velocities measured at 15 - 20 m depth, with rms directional differences of about 60 deg. These differences compared favorably with a baseline difference estimate between ADCP vectors interpolated to drifter locations within a well-sampled region. High correlations between the AVHRR estimates and the coincident Geosat geostrophic velocity profiles suggested that the AVHRR methods adequately resolved the important flow features. The flow field was determined to consist primarily of a meandering southward flowing current, interacting with several eddies, including a strong anticyclonic eddy to the north of the jet. Incorporation of sparse altimeter data into the AVHRR estimates gave a modest improvement in comparisons with in situ data. Author

ACOUSTIC MONITORING OF GLOBAL OCEAN VARIABILITY Final Report, 1 Nov. 1991 - 28 Feb. 1993
Walter H. Munk 10 Oct. 1993 39 p Prepared in cooperation with Washington Univ., Seattle
(Contract MDA972-92-C-0019)
(AD-A271998; UCSD-92-1070) Avail: CASI HC A03/MF A01

Oceanic circulation is known to be a central element in determining the present climate state and to be crucial in understanding how it might change in the future. However, our current understanding of the ocean is so primitive that forecasts of future climate states must be regarded as speculative. Central to the problem is the great difficulty associated with observing the state of the ocean today and of determining whether it is changing to any significant extent. The concept of Acoustic Thermometry of Ocean Climate as described by this document focuses on the critical role of the world's oceans in the process of global change. A research and engineering program to create a network of acoustic transmission paths represents the first step to measure long-term temperature change in the ocean (and hence by inference, atmospheric and climatic trends). This network can build on the results of The Heard Island Feasibility Test by using very long-range underwater sound transmissions to measure oceanic temperature on basin scales. It involves a multiyear program to monitor the ocean on a global basis by installing a system of acoustic sources and receives at sites that provide adequate spatial sampling, and are technically, politically, and logistically feasible. DTIC

OCEAN WAVE HEIGHT TRANSFORMATION MODEL USING SURFACE ROLLER THEORY M.S. Thesis
A. H. Brookins Jun. 1993 49 p
(AD-A272610) Avail: CASI HC A03/MF A01

A wave height transformation model is developed using surface roller theory. Roller energy production is included in the energy flux balance equation to predict rms wave height for randomly varying, irregular waves over arbitrary bathymetry. The dissipation function is defined using wave roller theory, where the area of the roller is defined from a simple bore analogy. The Rayleigh distribution is used to statistically describe wave heights as waves shoal, break, and dissipate. Model predictions are compared with data acquired on both barred and near planar beaches. The surface roller wave height transformation model predicts rms wave heights with an average rms error of 6.5% for a barred beach over three days, 3.0% for two planar beaches over four days, and 4.5% average error for all locations over seven days. The model has two free parameters, alpha representing the type of breaker and gamma a measure of breaking wave saturation, also a function of beach slope. Optimal values of both parameters are chosen by model fitting. The model is sensitive to gamma, but not sigma. The surface roller model improves the bore dissipation model by decreasing the average rms error by 40% while decreasing model sensitivity to input parameters. DTIC

GREEN SHEET PROJECT: DYE SHEET EVOLUTION Interim Report, Dec. 1991 - Dec. 1992
C. L. Trump 30 Sep. 1993 54 p
(AD-A272019; NRL/MR/7340-93-7402) Avail: CASI HC A04/MF A01

A 300-kHz Acoustic Doppler Current Profiler (ADCP) was used aboard the USNS Bartlett as part of the Green Sheet 91 experiment during June 1991 in the Gulf of Mexico. The purpose of the experiment was to lay out a sheet of dye at the bottom of the mixed layer for later sampling by an airborne LIDAR system. Ship's tracks relative to targeted depths were calculated to reconstruct the dye deployment and sampling process. During the practice deployment, termed Dress Rehearsal, a small front was found between the second and third leg which adversely affected the location and geometry of the dye sheet. During the first LIDAR test, termed Flight One, currents rotating strongly in depth and weakly in the horizontal also adversely affected the character of the final dye sheet. A Shear-Advection model was developed, using ADCP data and concurrently recorded navigation data, to predict the dye sheet evolution. The results of the model helped understand the evolution of dye sheets and were in agreement with the results of the LIDAR sampling during Flight One. For future Green Sheet experiments the ADCP should be used to provide real-time ship's tracks relative to a given water depth to aid dye deployment. The Shear-Advection model should be used in near-real-time to aid the vectoring of the plane over the evolved dye sheet. DTIC

PRESENTING THE RAIN-SEA INTERACTION FACILITY
Larry F. Bliven and Tonas M. Elfouhaily (Paris V Univ., France.) Nov. 1993 36 p Sponsored by NASA. Washington
(NASA-RP-1322; NAS 1.61:1322; Rept-94B00012) Avail: CASI HC A03/MF A01

The new Rain-Sea Interaction Facility (RSIF) was established at GSFC/WFF and the first finds are presented. The unique feature of this laboratory is the ability to systematically study microwave scattering from a water surface roughened by artificial rain, for which the droplets are at terminal velocity. The fundamental instruments and systems (e.g., the rain simulator, scatterometers, and surface elevation probes) were installed and evaluated during these first experiments - so the majority of the data were obtained with the rain simulator at 1 m above the water tank. From these initial experiments, three new models were proposed: the square-root function for NCS vs. R, the log Gaussian model for ring-wave elevation frequency spectrum, and the Erland probability density distribution for back scattered power. Rain rate is the main input for these models, although the coefficients may be dependent upon other factors (drop-size distribution, fall velocity, radar configuration, etc.). The facility is functional and we foresee collaborative studies with investigators who are engaged in measuring and modeling rain-sea interaction processes. Author (revised)

Electron diffraction data and high resolution images can now be used to obtain accurate, three-dimensional density maps of biological macromolecules. These density maps can be interpreted by building an atomic-resolution model of the structure into the experimental density. The Cowley-Moodie formalism of dynamical diffraction theory was used to validate the use of kinematic diffraction theory, strictly the weak phase object approximation, in producing such 3-D density maps. Further improvements in the preparation of very flat specimens and in the retention of diffraction to a resolution of 0.2 nm or better could result in electron crystallography becoming as important a technique as x ray crystallography currently is for the field of structural molecular biology. SELF-MOTION PERCEPTION AND MOTION SICKNESS Final Report, 1982 - 1991
Robert A. Fox (San Jose State Univ., CA.) 1991 150 p
(Contract NCC2-167)
(NASA-CR-194276; NAS 1.26:194276) Avail: CASI HC A07/MF A02

Motion sickness typically is considered a bothersome artifact of exposure to passive motion in vehicles of conveyance. This condition seldom has significant impact on the health of individuals because it is of brief duration, it usually can be prevented by simply avoiding the eliciting condition and, when the conditions that produce it are unavoidable, sickness dissipates with continued exposure. The studies conducted examined several aspects of motion sickness in animal models. A principle objective of these studies was to investigate the neuroanatomy that is important in motion sickness with the objectives of examining both the utility of putative models and defining neural mechanisms that are important in motion sickness. For individual titles, see N94-21898 through N94-21915.

CHANGES IN PLASMA VASOPRESSIN DURING MOTION SICKNESS IN CATS Abstract Only
Robert Fox (San Jose State Univ., CA.), L. Keil, Nancy G. Daunton, D. Thomsen (San Jose State Univ., CA.), M. Dictor (San Jose State Univ., CA.), and O. Chee (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 1 p Repr. from Neuroscience Abstracts, v. 6, 1980 p 656 (For primary document see N94-21897 05-51)
Avail: CASI HC A01/MF A02

Changes in levels of plasma vasopressin (AVP) and cortisol (C) have been shown to be correlated with motion sickness and nausea in man. As part of the research aimed at validation of the cat as an appropriate animal model for motion sickness research, levels of these hormones were investigated in the cat during motion sickness elicited by vertical linear acceleration of approximately 0.6 Hz and 1 +/- 0.6 G. In Study 1, 15 cats previously screened for susceptibility to motion sickness were prepared with indwelling jugular catheters to permit withdrawl of blood with minimal disruption of the stimulus and minimum stress to the animal. AVP and C were measured in blood samples obtained during exposure to vertical linear acceleration and during control sessions in which the animals were placed in the stationary apparatus. 10 min and 1 min prior to duration; 1, 5, 10, and 20 min after start of motion. Total duration of exposure to motion was 20 min. The data indicate that both AVP and C are elevated during exposure to motion if emesis occurs. AVP reaches maximum levels during or about the same time as emesis, while C increases gradually throughout the period of vertical acceleration. In Study 2, four cats were prepared with indwelling catheters and AVP was measured in blood withdrawn during exposure to the vertical linear acceleration. A single pre-motion sample consisting of three samples drawn 5 min prior to motion onset. Two series of samples consisting of three samples drawn at 3-min intervals were obtained during motion. The first series was initiated at emesis, and the second 25 min after emesis. Results show that levels of circulating AVP were elevated (2 to 27 times the control and pre-motion levels) in the samples taken during emesis and decreased, but remained 1 to 6 times above the pre-motion or control levels within 25 min. The results of these two studies indicate that AVP is elevated during motion-produced emesis than is C. These findings are in general agreement with those obtained from humans under motion sickness conditions, and indicate that it is appropriate to continue to use the cat in studies of hormone changes during motion sickness. SUSCEPTIBILITY OF THE SQUIRREL MONKEY TO DIFFERENT MOTION CONDITIONS Abstract Only
Robert A. Fox (San Jose State Univ., CA.), Nancy G. Daunton, and J. Coleman (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 1 p Repr. from Neuroscience Abstracts, v. 8, 1982 p 698 (For primary document see N94-21897 05-51)
Avail: CASI HC A01/MF A02

The exact stimulus eliciting vomiting in animal studies of motion sickness is difficult to specify because the vestibular stimulation produced by many motion conditions is confounded by voluntary movements with animals. This is an important problem because experiments with animal models of motion sickness can provide useful information about antimotion sickness drugs or the role of neural mechanisms, only when animals are exposed to the same motion stimuli in each experimental session. A series of tests were conducted to determine the susceptibility of 15 adult squirrel monkeys to motion sickness in freely moving and restrained test conditions. Canal stimulation was varied by exposing the monkey in freely moving conditions to varying degrees of angular velocity (60, 90, 120, 150 deg/sec), and in restrained conditions to one angular velocity (150 deg/sec) and to cross-coupling effects of whole-body roll movements during rotation. Otolith stimulation was investigated by using sinusoidal vertical linear acceleration during free movement conditions, and off-vertical rotation and earth-horizontal (BBQ) rotation while restrained. The percentage of freely moving animal vomiting during vertical axis rotation was 27, 93, 86, and 92 for the angular velocities of 60, 90, 120, and 150 deg/sec respectively. None of the monkeys vomited during vertical axis rotation or cross-coupled rotation when restrained. Otolith stimulation appears to be a less provocative stimulus for the squirrel monkey as the percentage of animals vomiting were 13, 0, and 7 for the conditions of free movement during oscillation, restraint during off-vertical, and BBQ rotation respectively. Motion sickness to the point of vomiting occurred regularly only in conditions where self-motion was possible. Such effects could occur because voluntary movement during motion augments vestibular effects by producing self-inflicted cross-coupling, but the failure to elicit vomiting with experimenter-coupling cross-coupling argues against this interpretation. Alternatively, these results might imply that feedback from movement control mechanisms may play an important role in sensory conflict as suggested by Oman's sensory-motor conflict theory. Author

RELATIONSHIP OF AREA POSTREMA TO THREE PUTATIVE MEASURES OF MOTION SICKNESS Abstract Only
R. Sutton (San Jose State Univ., CA.), Robert A. Fox (San Jose State Univ., CA.), and Nancy G. Daunton *In its* Self-Motion Perception and Motion Sickness 1991 1 p Repr. from unidentified source (For primary document see N94-21897 05-51)

Although the rat has an incomplete emetic reflex, several species-specific responses to motion were proposed as measures of 'motion sickness' in rats. The purpose was to determine the dependence of these responses on one of several neural structures known to be essential to motion-induced vomiting in species with a complete emetic reflex. The Area Postrema (AP) was shown to play an important role in the production of motion sickness in vomiting species. The effects of thermo-cautery ablations of the AP on three different responses supposedly reflecting motion sickness in the rat were compared: conditioned taste aversion (CTA); drinking suppression; and fecal boli. Efficacy of the ablations was determined by subjecting ablated, sham-operated, and unoperated control animals to a CTA test which is known to require a functional AP. Animals with AP ablations failed to form CTA when 0.15 M LiCl was paired with a 10 percent sucrose solution, while sham-operated control subjects conditioned as well as the unoperated control subjects. The extent of the ablations was evaluated histologically at the end of the experiment. To determine the effects of the ablations on the measures of motion sickness, all animals were subjected to rotation for 30 min or 90 min on a platform displaced 20 deg from earth horizontal. Results indicate that ablation of AP in the

rat has no effect on the formation of CTA to a 4 percent solution of cider paired with motion, on the suppression of drinking immediately after exposure to motion, or on the frequency of fecal boli during exposure to motion. This failure of AP ablations to eliminate the effects of motion on any of these responses discourages their use as equivalents of motion-induced vomiting. The appropriateness of other suggested measures, e.g., pica, remains untested but the dependence of such measures on stimulation more severe than commonly used in motion sickness research and the absence of a demonstration of their dependence on neural structures essential to motion sickness in vomiting species, suggest caution in the use of such responses. Further, until more is known about the neural structures underlying these putative measures, the rat will remain a questionable subject in which to study motion sickness. Author (revised)

Avail: CASI HC A01/MF A02

On the basis of classical studies on the role of the area psotrema (AP) in motion-induced emesis it was generally accepted that the AP is an essential structure for the production of vomiting in response to motion. However, in more recent studies it has been demonstrated that vomiting induced by motion can still occur in animals in which the AP has been destroyed bilaterally. It was inferred from some of these more recent studies that the AP plays no role in motion-induced emesis. From the standpoint of the current understanding of central nervous system (CNS) plasticity, redundancy, remodeling, unmasking, regeneration, and recovery of function, however, it is important to realize the limitations of using ablation procedures to determine the functional role of a given neural structure in a highly integrated, adaptable central nervous system (CNS). For example, the results of our recent investigations in cat and squirrel monkey on the role of the AP in emesis and conditioned taste aversion induced by motion indicate that while AP lesions do not prevent motion-induced emesis when animals are tested 30 days or more after surgery, the lesions do change the latency to emesis. Thus, contradictory findings from lesion studies must be evaluated not only in terms of species difference, differences in lesioning techniques and extent of lesions, and in stimulus parameters, but also in terms of duration of the recovery period, during which significant recovery of function may take place. In our judgment, inadequate consideration of the foregoing factors could lead to erroneous inferences about given structure's role in the behavior of the intact, nonablated animal. Author (revised)

GAMMA-AMINOBUTYRIC ACID (GABA) AND NEUROPEPTIDES IN NEURAL AREAS MEDIATING MOTION-INDUCED EMESIS Abstract Only

F. DAmelio, Nancy G. Daunton, and Robert A. Fox *In its* Self-Motion Perception and Motion Sickness 1991 1 p Repr. from Chinese J. Physiological Sciences, v. 3, 1987, p 443-444 (For primary document see N94-21897 05-51)

Avail: CASI HC A01/MF A02

Immunocytochemical methods were employed to localize the neurotransmitter amino acid gamma-aminobutyric acid and the neuropeptides substance P and Met-enkephalin in the area postrema (AP), area subpostrema (ASP), nucleus of the tractus solitarius (NTS), dorsal motor nucleus of the vagus nerve (DMNV), and lateral vestibular nucleus (LVN). Glutamic acid decarboxylase immunoreactive (GAD-IR) terminals and fibers were observed in the AP and particularly in the ASP. A gradual decrease in the density of terminals was seen towards the solitary complex. The DMNV revealed irregularly scattered GAD-IR terminals within the neuropil or closely surrounding neuronal cell bodies. The LVN, particularly the dorsal division, showed numerous axon terminals which were mostly localize around large neurons and their proximal dendrites. Substance P immunoreactive (SP-IR) terminals and fibers showed high density in the solitary complex, in particular within the lateral division. The ASP showed medium to low density of SP-IR fibers and terminals. The AP exhibited a small number of fibers and terminals irregularly distributed. The DMNV revealed a high density of SP-IR terminals and fibers that were mainly concentrated in the periphery. Very few terminals were detected in the LVN. Met-enkephalin immunoreactive (Met-Enk-IR) fibers and terminals showed high density and uniform distribution in the DMNV. Scattered terminals and fibers were observed in the AP, ASP, and NTS (particularly the lateral division). The very few fibers were observed in the LVN surrounded the neuronal cell bodies. The present report is part of a study designed to investigate the interaction between neuropeptides and conventional neurotransmitters under conditions producing motion sickness and in the process of sensory-motor adaptation. DETECTION OF EMETIC ACTIVITY IN THE CAT BY MONITORING VENOUS PRESSURE AND AUDIO SIGNALS Abstract Only

A. Nagahara (San Jose State Univ., CA.), Robert A. Fox (San Jose State Univ., CA.), Nancy G. Daunton, and S. Elfar *In its* Self-Motion Perception and Motion Sickness 1991 1 p Repr. from Neuroscience Abstracts, v. 12, Nov. 1986 (For primary document see N94-21897 05-51)

Avail: CASI HC A01/MF A02

To investigate the use of audio signals as a simple, noninvasive measure of emetic activity, the relationship between the somatic events and sounds associated with retching and vomiting was studied. Thoracic venous pressure obtained from an implanted external jugular catheter was shown to provide a precise measure of the somatic events associated with retching and vomiting. Changes in thoracic venous pressure monitored through an indwelling external jugular catheter with audio signals, obtained from a microphone located above the animal in a test chamber, were compared. In addition, two independent observers visually monitored emetic episodes. Retching and vomiting were induced by injection of xylazine (0.66mg/kg s.c.), or by motion. A unique audio signal at a frequency of approximately 250 Hz is produced at the time of the negative thoracic venous pressure change associated with retching. Sounds with higher frequencies (around 2500 Hz) occur in conjunction with the positive pressure changes associated with vomiting. These specific signals could be discriminated reliably by individuals reviewing the audio recordings of the sessions. Retching and those emetic episodes associated with positive venous pressure changes were detected accurately by audio monitoring, with 90 percent of retches and 100 percent of emetic episodes correctly identified. Retching was detected more accurately (p is less than .05) by audio monitoring than by direct visual observation. However, with visual observation a few incidents in which stomach contents were expelled in the absence of positive pressure changes or detectable sounds were identified. These data suggest that in emetic situations, the expulsion of stomach contents may be accomplished by more than one neuromuscular system and that audio signals can be used to detect emetic episodes associated with thoracic venous pressure changes. RECOVERY OF THE VOMITING REFLEX FOLLOWING AREA POSTREMA ABLATION IN SQUIRREL MONKEYS

S. Elfar, Kenneth R. Brizzee (Tulane Univ., Covington, LA.), Robert A. Fox (San Jose State Univ., CA.), Meryl Lee Corcoran, Nancy G. Daunton, and J. Coleman (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 5 p Repr. from Neuroscience Abstracts, v. 12, Nov. 1986 (For primary document see N94-21897 05-51)

Avail: CASI HC A01/MF A02

The role of the area postrema (AP) in motion-induced emesis was re-assessed recently in several different species. In a few of these studies, the role of the AP in motion-induced conditioned taste aversion (CTA) was also addressed. The purpose was to extend this comparative study to the squirrel monkey, to evaluate further the role of AP in vomiting, and to investigate the dynamics of the recovery process. The AP was ablated bilaterally in 7 motion-susceptible squirrel monkeys which previously had been characterized in terms of their responses to various motion sickness-inducing stimuli. After recovery from surgery all animals were tested at 30-day intervals for a period of 11 months to determine the effects of AP ablations on susceptibility to the same sickness-inducing conditions. In

addition, the effectiveness of motion in producing CTA was evaluated. All pre-ablation motion tests involved stimulation for 30 min., while post-lesion tests were 60 min., in duration. All animals showed significant increases in latencies to vomiting after AP ablations. However, the latencies tended to decrease with time after ablation. All but one animal vomited on at least one of the 10 motion tests occurring after ablation of AP. In addition, CTA was produced by motion used in the conditioning sessions. These results suggest that structures other than AP, and processes other that those mediated through AP, may play an important role in motion-induced emesis. Author (revised)

MOTION SICKNESS ELICITED BY PASSIVE ROTATION IN SQUIRREL MONKEYS

Nancy G. Daunton and Robert A. Fox (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 2 p Repr. from Vestibular and Visual Control on Posture and Locomotion Equilibrium, 1983 p 164-169 (For primary document see N94-21897 05-51)
(Contract NCA2-OR-675-801; NIH-S06RR08192-02)
Avail: CASI HC A01/MF A02

Current theory and recent evidence suggest that motion sickness occurs under conditions of sensory input in which the normal motor programs for producing eye, head, and body movements are not functionally effective, i.e. under conditions in which there are difficulties in maintaining posture and controlling eye movements. Conditions involving conflicting or inconsistent visual-vestibular (VV) stimulation should thus result in greater sickness rates since the existing motor programs do not produce effective control of eye-head-body movements under such conditions. It is felt that the relationship of postural control to motion sickness is an important one and one often overlooked. The results are reported which showed that when postural requirements were minimized by fully restraining squirrel monkeys during hypogravity parabolic flight, no animals became motion sick, but over 80 percent of the same 11 animals became sick if they were unrestrained and maintained control of their posture.

AREA POSTREMA ABLATIONS IN CATS: EVIDENCE FOR SEPARATE NEURAL ROUTES FOR MOTION- AND XYLAZINE-INDUCED CTA AND EMESIS Abstract Only

Meryl Lee Corcoran, Robert A. Fox (San Jose State Univ., CA.), Kenneth R. Brizzee (Tulane Univ., Covington, LA.), G. Crampton (Wright State Univ., Dayton, OH.), and Nancy G. Daunton *In its* Self-Motion Perception and Motion Sickness 1991 1 p Repr. from The Physiologist, v. 28., no. 4, Aug. 1985 (For primary document see N94-21897 05-51)
Avail: CASI HC A01/MF A02

Previous studies on the role of the area postrema (AP) in vomiting induced in the cat by motion and drugs have shown that the AP is not essential for motion-induced vomiting, but is necessary for vomiting to apomorphine and xylazine. To confirm these findings and to determine the role of the AP in the formation of Conditioned Taste Aversion (CTA), the AP was ablated bilaterally in 10 adult female cats. With one exception, the ablated cats continued to vomit to the same motion that elicited emesis before the ablation. Doses of xylazine and apomorphine that elicit emesis in intact cats, failed to induce emesis in the ablated cats. Histological examination indicated that 8 cats had complete lesions and 2 had partial lesions. Investigations of effects of AP ablations on CTA revealed that cats with complete lesions did not form CTA to flavored milk paired with xylazine-induced CTA. Seven of the eigth completely lesioned cats developed motion-induced CTA, even though emesis was not consistently elicited by motion. These results suggest that there are multiple routes for inducing CTA and the emetic reflex, that CTA can form without eliciting emesis, and that CTA may be a sensitive measure of sub-emetic motion sickness.

EFFECT OF COPPER SULPHATE ON THE RATE OF AFFERENT DISCHARGE IN THE GASTRIC BRANCH OF THE VAGUS NERVE IN THE RAT

Akira Niijima (Niigata Univ., Japan.), Zheng-Yao Jiang (Niigata Univ., Japan.), Nancy G. Daunton, and Robert A. Fox (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 4 p Repr. from Neuroscience Letters, v. 80, 1987 p 71-74 (For primary document see N94-21897 05-51)
Avail: CASI HC A01/MF A02

The afferent nerve activity was recorded from a nerve filament isolated from the peripheral cut end of the gastric branch of the vagus nerve. The gastric perfusion of 4 ml of two different concentrations (0.04 percent and 0.08 percent) of CuSO4 solution provoked an increase in afferent activity. The stimulating effect of the 0.08 percent solution was stronger than that of the 0.04 percent solution, and lasted for a longer period of time. The observations suggest a possible mechanism by which CuSO4 elicits emesis. Author (revised)

CONDITIONED TASTE AVERSION INDUCED BY MOTION IS PREVENTED BY SELECTIVE VAGOTOMY IN THE RAT

Robert A. Fox (San Jose State Univ., CA.) and Susan McKenna (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 10 p Repr. from Behavioral and Neural Biology, v. 50, 1988 p 275-284 (For primary document see N94-21897 05-51)
(Contract NCC2-1421)
Avail: CASI HC A02/MF A02

The role of the vagus nerve in motion-induced conditioned taste aversion (CTA) was studied in hooded rats. Animals with complete, selective gastric vagotomy failed to form conditioned taste aversion after multiple conditioning sessions in which the conditioned stimulus (a cider vinegar solution) was drunk immediately before a 30-min exposure to vertical axis rotation at 150 deg/s. Results are discussed with reference to the use of CTA as a measure of motion-induced 'sickness' or gastrointestinal disturbance, and because motion-induced CTA requires that both the vagus nerve and the vestibular apparatus be intact, in light of the possible convergence of vegal and vestibular functions. IMMUNOCYTOCHEMICAL LOCALIZATION OF GLUTAMIC ACID DECARBOXYLASE (GAD) AND SUBSTANCE P IN NEURAL AREAS MEDIATING MOTION-INDUCED EMESIS: EFFECTS OF VAGAL STIMULATION ON GAD IMMUNOREACTIVITY

F. DAmelio (San Jose State Univ., CA.), M. A. Gibbs, W. R. Mehler, Nancy G. Daunton, and Robert A. Fox (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 12 p Repr. from Basic and Applied Aspects of Vestibular Function, 1988 (For primary document see N94-21897 05-51)
Avail: CASI HC A03/MF A02

Immunocytochemical methods were employed to localize the neurotransmitter amino acid gamma-aminobutyric acid (GABA) by means of its biosynthetic enzyme glutamic acid decarboxylase (GAD) and the neuropeptide substance P in the area postrema (AP), area subpostrema (ASP), nucleus of the tractus solitarius (NTS), and gelatinous nucleus (GEL). In addition, electrical stimulation was applied to the night vagus nerve at the cervical level to assess the effects on GAD-immunoreactivity (GAR-IR). GAD-IR terminals and fibers were observed in the AP, ASP, NTS, and GEL. They showed pronounced density at the level of the ASP and gradual decrease towards the solitary complex. Nerve cells were not labelled in our preparations. Ultrastructural studies showed symmetric or asymmetric synaptic contracts between labelled terminals and non-immunoreactive dendrites, axons, or neurons. Some of the labelled terminals contained both clear- and dense-core vesicles. Our preliminary findings, after electrical stimulation of the vagus nerve, revealed a bilateral decrease of GAD-IR that was particularly evident at the level of the ASP. SP-immunoreactive (SP-IR) terminals and fibers showed varying densities in the AP, ASP, NTS, and GEL. In our preparations, the lateral sub-division of the NTS showed the greatest accumulation. The ASP showed medium density of immunoreactive varicosities and terminals and the AP and GEL displayed scattered varicose axon terminals. The electron microscopy revealed that all immunoreactive terminals contained clear-core vesicles which make symmetric or asymmetric synaptic contact with unlabelled dendrites. It is suggested that the GABAergic terminals might correspond to vagal afferent

projections and that GAD/GABA and substance P might be co-localized in the same terminal allowing the possibility of a regulated release of the transmitters in relation to demands. Author (revised)

THE EFFECTS OF AREA POSTREMA LESIONS AND SELECTIVE VAGOTOMY ON MOTION-INDUCED CONDITIONED TASTE AVERSION

Robert A. Fox (San Jose State Univ., CA.), R. L. Sutton (California Univ., Los Angeles.), and Susan McKenna (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 6 p Repr. from Basic and Applied Aspects of Vestibular Function, 1988 (For primary document see N94-21897 05-51)

Avail: CASI HC A02/MF A02

Conditioned taste aversion (CTA) is one of several behaviors which was suggested as a putative measure of motion sickness in rats. A review is made of studies which used surgical disruption of area postrema or the vagus nerve to investigate whether CTA and vomiting induced by motion may depend on common neural pathways or structures. When the chemoreceptive function of the area postrema (AP) is destroyed by complete ablation, rats develop CTA and cats and monkeys develop CTA and vomit. Thus the AP is not crucially involved in either CTA or vomiting induced by motion. However, after complete denervation of the stomach or after labyrinthectomy rats do not develop CTA when motion is used as the unconditioned stimulus. Studies of brainstem projections of the vagus nerve, the area postrema, the periaqueductal grey, and the vestibular system are used as the basis for speculation about regions which could mediate both motion-induced vomiting and behavioral food aversion. EXPERIMENTAL STUDIES OF GASTRIC DYSFUNCTION IN MOTION SICKNESS: THE EFFECT OF GASTRIC AND VESTIBULAR STIMULATION ON THE VAGAL AND SPLANCHNIC GASTRIC EFFERENTS

A. Niijima (Niigata Univ., Japan.), Z. Y. Jiang (Niigata Univ., Japan.), Nancy G. Daunton, and Robert A. Fox (San Jose State Univ., CA.) *In its* Self-Motion Perception and Motion Sickness 1991 10 p Repr. from Basic and Applied Aspects of Vestibular Function, 1988 (For primary document see N94-21897 05-51)

Avail: CASI HC A02/MF A02

The experiments were conducted in anaesthetized rats. In the first part of the experiments, the effect of CuSO4 on the afferent activity in the gastric branch of the vagus nerve was investigated. Gastric perfusion of CuSO4 solution (0.04 percent and 0.08 percent) provoked an increase in afferent activity. In the second part of the experiments, the reflex effects of gastric perfusion of CuSO4 solution, repetitive stimulation of the gastric vagus nerve, and caloric stimulation of the right vestibular apparatus (5-18 C water) on gastric autonomic outflow were investigated. The results of these experiments showed that these three different types of stimulation caused an inhibition in efferent activity of the gastric vagus nerve and a slight activation of the splanchnic gastric efferents. The summation of the effect of each stimulation was also observed. These results, therefore, provide evidence for a possible integrative inhibitory function of the vagal gastric center as well as an excitatory function of gastric sympathetic motoneurons in relation to motion sickness. ROLE OF THE AREA POSTREMA IN THREE PUTATIVE MEASURES OF MOTION SICKNESS IN THE RAT

Richard L. Sutton (San Jose State Univ., CA.), Robert A. Fox (San Jose State Univ., CA.), and Nancy G. Daunton *In its* Self-Motion Perception and Motion Sickness 1991 20 p Repr. from Behavioral and Neural Biology, v. 50, 1988 p 133-152 (For primary document see N94-21897 05-51)

Avail: CASI HC A03/MF A02

After thermal cauterization of the area postrema in rats, the absence of conditioned taste aversion of sucrose paired with lithium chloride (0.15M, 3.3 ml/kg) was used as a pharmacologic/behavioral index of area postrema damage. In a subsequent experiment the effects of area postrema lesions on three measures proposed as species-relevant measures of motion sickness were studied, using off-vertical rotation at 150 deg/s for either 30 or 90 min. Lesions of area postrema did not alter postrotational suppression of drinking or amount of defecation during motion. The initial acquisition of conditioned taste aversion to a novel cider vinegar solution paired with motion was not affected by lesioning of the area postrema, but these taste aversions extinguished more slowly in lesioned rats than in sham-operates or intact controls. Results are discussed in terms of proposed humoral factors which may induce motion sickness and in light of recent data on the role of the area postrema in similar measures in species possessing the complete emetic reflex. The avoidance of foods which are associated with uncomfortable or aversive internal states has long been recognized. Many people are aware, either directly or via anecdotal reports, of individuals who avoid foods which were eaten just before the onset of sickness. Awareness of this phenomenon can be traced to the writings of John Locke. The disruption of diet during cancer therapy is sometimes ascribed to the attribution of an unpleasant quality to foods eaten preceding the sickness induced by therapy itself. In addition, it has long been recognized by the manufacturers of rodent poisons that animals avoid the injection of food treated with nonlethal doses of poison. An important part of the laboratory study of this phenomenon was directed toward studying the role learning plays in this type of avoidance behavior. Following the lead of Garcia and his associates, this avoidance has come to be interpreted as arising from a form of classical conditioning. In typical laboratory studies of this bahavior, a novel food is ingested just prior to exposure to some stimulus, commonly poisoning or irradiation, which produces illness. Following the terminology of classical conditioning, it is common to describe this procedure as one of 'pairing' a conditioned stimulus (CS), the novel food, with an unconditioned stimulus (US), the illness induced by toxicosis or irradiation. Avoidance of the food in succeeding feeding opportunities is viewed as a learned response or a conditioned taste aversion (CTA). Garcia et al. asserted that motion sickness could produce 'gustatory' aversions, but passive motion was first reported as an US to establish CTA by Green and Rachlin. The purpose is to review the manner in which CTA has been used to study motion sickness. Numerous reviews concentrating on other aspects of CTA are available in the existing literature. Readers are encouraged to consult the various papers and edited books for extensive information on other aspects of this literature. Author (revised)

CONDITIONED TASTE AVERSION AND MOTION SICKNESS IN CATS AND SQUIRREL MONKEYS

Robert A. Fox (San Jose State Univ., CA.), Meryl Lee Corcoran, and Kenneth R. Brizzee (Tulane Univ., Covington, LA.) *In its* Self-Motion Perception and Motion Sickness 1991 10 p Repr. from unidentified source (For primary document see N94-21897 05-51)

Avail: CASI HC A02/MF A02

The relationship between vomiting and conditioned taste aversion was studied in intact cats and squirrel monkeys and in cats and squirrel monkeys in which the area postrema was ablated by thermal cautery. In cats conditioned 7-12 months after ablation of the area postrema, three successive treatments with xylazine failed to produce either vomiting or conditioned taste aversion to a novel fluid. Intact cats, however, vomited and formed a conditioned aversion. In squirrel monkeys conditioned 6 months after ablation of the area postrema, three treatments with lithium chloride failed to produce conditioned taste aversion. Intact monkeys did condition with these treatments. Neither intact nor ablated monkeys vomited or evidenced other signs of illness when injected with lithium chloride. When the same ablated cats and monkeys were exposed to a form of motion that produced vomiting prior to surgery, conditioned taste aversion can be produced after ablation of the area postrema. The utility of conditioned taste aversion as a measure of subemetic motion sickness is discussed by examining agreement and disagreement between identifications of motion

sickness by conditioned taste aversion and vomiting. It is suggested that a convincing demonstration of the utility of conditioned taste aversion as a measure of nausea requires the identification of physiological correlates of nausea, and caution should be exercised when attempting to interpret conditioned taste aversion as a measure of nausea. CURRENT STATUS: ANIMAL MODELS OF NAUSEA
Robert A. Fox *In* NASA. Ames Research Center, Self-Motion Perception and Motion Sickness 1991 10 p Repr. from Mechanisms and Control of Emesis, v. 223, 1992 p 341-350 (For primary document see N94-21897 05-51)
Avail: CASI HC A02/MF A02

The advantages, and possible benefits of a valid, reliable animal model for nausea are discussed, and difficulties inherent to the development of a model are considered. A principle problem for developing models arises because nausea is a subjective sensation that can be identified only in humans. Several putative measures of nausea in animals are considered, with more detailed consideration directed to variation in cardiac rate, levels of vasopressin, and conditioned taste aversion. Demonstration that putative measures are associated with reported nausea in humans is proposed as a requirement for validating measures to be used in animal models. The necessity for a 'real-time' measure of nausea is proposed as an important factor for future research; and the need for improved understanding of the neuroanatomy underlying the emetic syndrome is discussed.

In March 1985, flight academy applicants selected from eight middle schools received physical examinations in Gong'an County. These male students' ages were between 16 and 19 years old. The overall disqualification percentage of the 416 persons, 64.18 percent were disqualified by the results of the physical examinations. 40.82 percent of the disqualifications were due to subnormal eye vision. In a follow-up investigation, it was found that in general there is substandard classroom lighting below normal illumination levels regulated by the Ministry of Public Health. These subnormal illumination levels have affected student visual acuity in varying degrees. Persons with scabies were amounted to 7.11 percent of all students, spread easily in most schools because of undesirable dormitory conditions. To improve student body constitution, schools should emphasize education in student health maintenance and public health by paying attention to keeping their eyes healthy as well as eye exercises. The goal of this study was to develop a physiologically based pharmacokinetic (PBPK) model that predicts mammalian blood concentrations of dibromomethane following exposure by dermal absorption more accurately than a previously developed Homogeneous Dermal Model. The Homogeneous Dermal Model contains a dermal compartment with no dermal sub-compartments. The 1:1 Dermal Model developed in this research contains a dermal compartment with a stratum corneum and a composite dermal sub-compartment of equal volume. This model yields predictions which are 21.4 percent more accurate than the original homogeneous model. In order to represent skin anatomy more accurately, the 1:10 Dermal Model variation was developed. The 1:10 Dermal model contains a dermal compartment with a composite dermal sub-compartment ten times the volume of the stratum corneum sub-compartment. The 1:10 Dermal Model yields predictions which are 17.7 percent more accurate than the original model. Finally, the 1:3:7 Dermal Model was developed which contains a viable epidermis sub-compartment three times the volume of the stratum corneum sub-compartment and a composite dermal sub-compartment which is seven times the volume of the stratum corneum sub-compartment. This model yields predictions 27.7 percent more accurate than the original model. DTIC

A CONCEPT FOR IMPLEMENTING HYPERMEDIA TECHNOLOGY IN COMPUTER AIDED WORKPLACES IN MEDICINE Ph.D. Thesis [EIN KONZEPT FUER DEN EINSATZ DER HYPERMEDIATECHNIK AN COMPUTERGESTUETZTEN ARBEITSPLAETZEN IN DER MEDIZIN]
Michael Henke 1993 214 p In GERMAN
(ETN-93-95057) Avail: CASI HC A10/MF A03

A concept that allows medical personnel to structure the information about a patient is presented. It is assumed that the digital data is increasingly displacing the analog part and also that in addition to images, more and more other media (animation, video, text, graphics, charts etc.) will become an integral part of the digital patient folder. The result of the activities of the medical personnel that are involved in the patient's treatment is that there exists a strong relationship in the content of the documents which are created in that time. A report is related to medical images, a therapy plan is made on the basis of the diagnosis which refers to the reports and finally the results of the preliminary examination and the follow-up examination are compared for the purpose of therapy evaluation. Through a computer aided documentation of the relationship, that is by creating references between the documents of the patient folder, interdependencies will be easy to recognize and to duplicate later on. The aid that allows the connection of information in such a manner is realized with hypermedia technique. Through the application of the hypermedia technique, the structure of the patient folder results in a hypermedium. An expansion of this concept to several medical institutions gives additional advantages, such as comprehensive access to reference cases or the avoidance of repeated examinations. The success of the use of hypermedia techniques depends substantially on the design of the man machine communication. On the one hand new forms of interaction result from the demand to process multimedia data, on the other hand well designed user interfaces are needed to ensure an easy handling of the tools for creating and following up links. CALCULATION AND OPTIMIZATION OF ELECTROMAGNETIC FIELDS IN A PATIENT BY LOCAL HYPERTHERMIA UTILIZATION Ph.D. Thesis [BERECHNUNG UND OPTIMIERUNG ELEKTROMAGNETISCHER FELDER IM PATIENTEN BEI REGIONALEN HYPERTHERMIEANWENDUNGEN]
Jacek Nadobny 1993 168 p In GERMAN Sponsored by Deutschen Krebshilfe e.V., and Tech. Univ., Berlin, Germany Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-95059) Avail: CASI HC A08

Electric field intensities in an electrically inhomogeneous, lossy medium, near the source of the electromagnetic field, are calculated for estimation of the absorbed rate density distribution in human bodies. The volume surface integral equation formulation, in which a primary field is defined as the field put in the problem area, while the problem area is replaced by an inhomogeneous reference medium such as air is presented. Source distribution variations, due to reinstalled inhomogeneities, were defined as coupled sources and could be estimated as a problem part. The scatter field was defined as the difference between total and primary fields and was obtained as the sum of the fields generated by coupled sources and the polarization sources in the problem area. For numerical solution of equations, an iterative solver and a finite volume scheme were chosen. The method was tested from a medical point of view with an annular phased array, which creates an axially polarized electric field in the patient

tumor; temperature distributions were obtained by liquid crystal thermography and compared with calculations; the good agreement shows that the method is a useful tool for an optimized hypermedia treatment. ESA

THE ROLE OF AXON-SCHWANN CELL INTERACTIONS IN NERVOUS SYSTEM IONIC HOMEOSTASIS Final Report, 1 May 1988 - 30 Apr. 1993
Edward M. Lieberman 8 Jun. 1993 5 p
(Contract DAAL03-88-K-0102)
(AD-A270936; ARO-25752.10-LS) Avail: CASI HC A01/MF A01

The long term goal of the research program of this laboratory is to reach an understanding of the physiological interactions between neurons and their associated glia that relate to their ability to cooperatively regulate the ionic and neurohumoral milieu of the perineural and/or periaxonal space. To this end we have been investigating the mechanisms by which axons and neurons generate the chemical signals during their excitation that signals the glia to activate their metabolic and uptake processes that inactivate neurotransmitters preventing their accumulation to toxic concentrations and the transport of potassium and of sodium to maintain appropriate amounts of each ion in the perineural space thereby preserving excitability properties of the neural elements of the nervous system. For these investigations we have used the intact nerve fiber Schwann cell preparations of crayfish and squid to study nerve-Schwann cell interactions in intact systems and the mammalian Schwann cell culture to determine the generality of our findings to mammalian systems. TOWARD A NEUROBIOLOGICAL THEORY OF VISUAL ATTENTION Annual Report, 1 Sep. 1992 - 31 Aug. 1993
Christof Koch 30 Sep. 1993 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-J-0454)
(AD-A270724; AFOSR-93-0775TR) Avail: CASI HC A02

The investigators started the construction of a system-level simulation package incorporating the ideas of temporal tagging for attentional modulation of neuronal signals into a model of several interacting cortical and subcortical areas using video-camera acquired images. This simulation differs significantly from connectionist models, since the temporal structure of the neural signals plays a crucial role in the coding of attentional state. Thus, the simulation uses single neuron models with quasi-realistic temporal behavior. In particular, all models in which the activity of a neuron is measured only by average firing rate are excluded. Instead, the simulation assumes a spiking mechanism, and that the communication between neurons has to be accomplished by the exchange of potentials. DTIC

EVALUATION OF HEAD INJURY CRITERIA
Hamid M. Lankarani, Srinivas Reddy Malapati, and Rajiv Menon 1993 60 p
(NIAR-93-2) Avail: CASI HC A04/MF A01

Human safety is a major concern for those in airline industry and automobile industry. In order to improve the effectiveness and reduce the cost of vehicle safety, improved dummies and injury criteria are needed. A prerequisite for developing improved dummies is the development of injury tolerance of the human being to impacts like those caused in automobile accidents. One major problem of interest for aerospace and automotive designers is how to arrange seats, restraints and interior elements of a cockpit/cabin or a car to reduce the amount of passenger injury in specific types of collision situations. The use of Head Injury Criteria (HIC) in vehicle crash testing results in designing restraint systems. It is capable of predicting severity of human head injury. This knowledge can be applied to the development of improved design standards to reduce injuries in vehicle crash situations. According to the aerospace standards in designing seats, for civil rotor craft and transport airplanes HIC has to be evaluated during the tests on seats, and the results have to be included in the document. For these tests an anthropomorphic test dummy (ATD) shall be used to simulate each occupant. In this study an effort has been made to provide some details of the types of head injuries, the mechanisms associated with head injuries, some common definitions of terminologies related with head injuries, the historical development of various head injury criteria and their measures, some comparisons of the head injury criteria and computational aspects of head injury criteria. WIND CHILL: THE TEMPERATURE FEELING CAUSED BY THE WIND VELOCITY [WIND CHILL: DE DOOR DE WINDSNELHEID VEROORZAAKTE TEMPERATUURGEWAARWORDING]
B. Zwart Nov. 1992 42 p In DUTCH
(KNMI-TR-103a; ISBN-90-369-2029-9; ETN-94-94530) Avail: Issuing Activity (Royal Netherlands Meteorological Institute, Postbus 201, 3730 AE De Bilt, Netherlands)

The loss of heat of a body by the combination of low temperatures and high wind velocities was studied for the period around mid January 1987 when the weather conditions were extreme for the Netherlands. The concepts of sensory or apparent temperature and wind chill are introduced. The cooling speed of the body was determined with a Kata thermometer. The concepts of wind-chill equivalent and effective temperature are discussed. The effects of humidity and radiation on the apparent temperature are outlined. ESA

EXTRA-CORPOREAL BLOOD ACCESS, SENSING, AND RADIATION METHODS AND APPARATUSES Patent
Kent D. Castle, inventor (to NASA) 16 Nov. 1993 10 p Filed 16 Sep. 1991 Supersedes N92-11627 (30 - 2, p 289)
(NASA-Case-MSC-21775-1; US-Patent-5,261,874;
US-Patent-Appl-SN-760633; US-Patent-Class-604-4;
US-Patent-Class-604-28; Int-Patent-Class-A61M-1/03) Avail: US Patent and Trademark Office

The described invention is related to extra-corporeal blood access and radiation methods and apparatuses and, in particular, to subjecting flowing blood to energy in variety of forms, including radiation, electromagnetic force fields or atomic particles. It is directed to methods and apparatuses for accessing flowing blood and for subjecting the blood to electrical conductive, electrostatic or electromagnetic fields or for radiating the blood with some type of radiation, e.g., radio waves, ultrasonic or audio waves, microwaves, IR rays, visible light, UV radiation, x-rays, alpha, beta or gamma rays. An apparatus is employed which includes one or more access ports or windows for radiating blood and/or for sensing/analyzing blood. This invention is useful for killing viruses and bacteria in blood, monitoring blood for medical purposes, genetic modification of blood, and analyzing and/or treating blood components.

OCULAR DAMAGE INDUCED BY ULTRASHORT LASER PULSES Interim Technical Report, Feb. - Jul. 1992
Joseph A. Zuclich, W. R. Elliott, Clarence P. Cain, Gary D. Noojin, and W. P. Roach Sep. 1993 34 p
(Contract F33615-92-C-0017)
(AD-A271859; AL/OE-TR-1993-0099) Avail: CASI HC A03/MF A01

A study has been conducted of interaction effects and damage mechanisms of ultrashort laser pulses in the eye. The preliminary results

reported here utilized rabbit subjects and ocular tissues isolated from the rabbit eye. Pulsewidths ranged from 4 ns down to 90 fs. In every case, a visible wavelength was used--either doubled Nd:YAG at 532 nm or the 580-nm output of a pumped dye laser. In the living subjects, we determined, for each pulsewidth, the threshold for minimally visible lesions (MVL's). In addition, we noted the energy doses required to induce hemorrhagic lesions relative to the corresponding MVL's and use these data to aid in the interpretation of the damage and energy dispersal mechanisms following absorption of ultrashort laser pulses. The ultrashort-pulse beam was directed through flat preparations of rabbit corneas and vitreous fluid and through intact rabbit lenses. Measurements were made to detect pulsewidth broadening or modulation, spectral broadening or white-light continuum generation, second-harmonic generation, and self-focussing or defocussing. These measurements, chosen as indicators of interactions as the ultrashort pulse passes through the ocular medium, were all negative. DTIC

CORONARY ANGIOGRAPHY OUTCOMES OF US ARMY AIRCREW WITH THE FINDING OF CORONARY ARTERY CALCIFICATIONS: AVIATION EPIDEMIOLOGY DATA REGISTER Final Report
Kevin T. Mason, Samuel G. Shannon, and Paul V. Celio Jul. 1993 38 p
(AD-A271968; USAARL-93-28) Avail: CASI HC A03/MF A01

U.S. Army aircrew with a history of coronary artery calcification were identified by cardiac fluoroscopy, followed by coronary angiography, in the U.S. Army Aviation Epidemiology Data Registry for the period 1 January 1988 to 1 August 1992. Eighty-two aircrew met these criteria. Their angiography outcomes are summarized. The positive predictive value of cardiac calcifications for predicting any degree of coronary artery occlusion was 82.9%. The Framingham Risk Index, total serum cholesterol, cholesterol/HDL-cholesterol ratio, and results of the graded exercise treadmill test and thallium scan were not significant factors in predicting the angiography outcome when coronary artery calcifications were present. Aircrew in coronary artery disease screening programs should be examined for coronary artery calcifications by cardiac fluoroscopy and referred for coronary angiography if calcifications are seen. STUDIES OF NEURAL AND COGNITIVE FUNCTION IN SUBJECTS EXPOSED TO THE MARINE-AIR INTERFACE, PHASES 1 AND 2 Final Report
Lorentz E. Wittmers, Jr. and Richard G. Hoffman 26 Oct. 1993 162 p
(Contract N00014-88-K-0582)
(AD-A272282) Avail: CASI HC A08/MF A02

In Phase 1 the effects of cold air (c), water (w), fatigue (f), and exercise (e) on physiological and psychological performance, and the effectiveness of several techniques for the suppression of shivering were investigated in 15 male subjects. Cold exposure was determined to be the most significant factor in reducing performance, causing significant reductions (p less than or equal to 0.05) in skin and rectal temperatures, temperature perceptions, shooting performance, grip strength, and dexterity both alone or when combined with any or all other factors. Cognitive performance, however was highest in the c/w/e/f, control, and c conditions, with the overall scores in the c/w, c/w/f and c/w/e conditions significantly lower than control and c/w/e/f. Shivering gradually increased throughout exposure in cold conditions but was delayed in conditions which included exercise. Rectal temperatures increased during exercise, but later fell to the same level as in the non-exercise conditions. After 2+ hours of exposure 4 shiver-suppression techniques were applied: voluntary relaxation (R), breath holding (B), mental arithmetic (M), and warm water ingestion (W). Shivering was significantly suppressed by R, B, and M. In Phase 2 analysis of evoked potentials and reaction times during central and peripheral cooling indicated that cooling methods have differing effects on physiological and physical function. DTIC

PERCEPTION/ACTION: AN HOLISTIC APPROACH 2 Annual Technical Report, Aug. 1992 - Aug. 1993
John M. Flach 12 Oct. 1993 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-J-0511)
(AD-A271822; WSU/TR/662238-39; AFOSR-93-0820TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A general systems approach was used to study the emergent properties of the human perception/action system. Two task domains, the control of locomotion and the recognition of objects from dynamic occlusion, were used to study human performance. The locomotion task involved the control of altitude. Experimental results indicate that conflicting results from studies of altitude perception can be explained when global optical flow rate is considered. Optical analyses of the structure of flow fields, empirical results from human performance studies, and control theoretical analyses of the state space all converge to indicate that altitude and speed are not independent with respect to the problem of controlling locomotion in low altitude flight. In the dynamic occlusion task, the effects of time delays, visual noise, training, and instructions have been evaluated. The results tend to support the hypothesis that information was the critical determinant of performance in the dynamic occlusion task. Mode (active versus passive observer) was only important to the extent that it made additional information available to the observer. This conclusion is consistent with research on adaptation where the 'reafference hypothesis,' in which mode played an important role, is being replaced by the 'information hypothesis.' DTIC

REVIEW OF USING CARDIAC FLUOROSCOPY IN SYMPTOMATIC AND ASYMPTOMATIC PATIENTS Final Report
Kevin T. Mason Aug. 1993 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 3M1-62787-A-879)
(AD-A271690; USAARL-93-29) Avail: CASI HC A03

The history of methods to find coronary artery calcification is reviewed. Image-intensified cardiac fluoroscopy is the current method in general use for finding coronary artery calcifications. The technique of cardiac fluoroscopy is reviewed in detail. The findings of coronary angiography outcomes for symptomatic and asymptomatic populations with coronary artery calcifications are analyzed. There is a strong association between the finding of coronary artery calcification and the finding of anatomic coronary artery occlusions regardless of the patient's age or outcome of other cardiovascular disease tests. Patients with coronary artery calcifications are at a three-fold increased risk for premature mortality when followed over a five-year period. Clinicians should examine patients for coronary artery calcifications in stratified coronary artery disease screening programs. DTIC

DEVELOPMENT AND DEMONSTRATION OF A PERSONAL MONITORING SYSTEM FOR EXPOSURE TO HYDROGEN FLUORIDE
M. S. Young and J. P. Monat 1993 98 p
(Contract DE-FG05-79EV-10249)
(DE93-041273; DOE/EV-10249/T1) Avail: CASI HC A05/MF A02

A good, functional Hydrogen Fluoride Gasbadge dosimeter has been developed for sampling of airborne HF vapor. The device is small (7.7 cm x 5.4 cm x 1.9 cm) and can easily and conveniently be worn on one's lapel. It consists of polyethylene and polypropylene parts and a triethanolamine-impregnated polyproylene collection element. It is completely self contained requiring no pumps, impingers, or sampling tubes. Subsequent to sampling, the collection element is analyzed quickly and easily with a fluoride selective-ion electrode. Laboratory tests were conducted to determine precision, linearity, interference effects, influences of temperature and humidity, and collection element stability over time. Results of the tests indicate that the Abcor Gasbadge HF dosimeter is an excellent passive HF monitor for work spaces, and that results obtained with it are accurate within +/- 25 percent. These results have been corroborated in a field study. DOE

NON-IONIC SURFACTANTS IN THE TREATMENT OF THIRD DEGREE BURNS Final Report, 1 Feb. 1990 - 31 Jul. 1993
James C. McPherson 1 Sep. 1993 35 p
(Contract MIPR-90-MM0544)
(AD-A271582) Avail: CASI HC A03/MF A01

Pluronic polyols are non-ionic surfactants developed in the 1950's. They are block co-polymers or the ABA type where A is made up of ethylene oxide polymers and B is propylene oxide polymers. They differ only in their molecular weight. The Pluronic polyols were shown to be non-toxic.

This protocol evaluates their effect on third degree scald burn in a rat model, pluronic polyols were administered 30 minutes following a third degree scald burn to the chest of 300-320 gram male rats. Histological evaluation documented this burn. The Pluronic polyol was administered intravenously at a concentration of 12mm/1 with a dose of 8ml/kg body weight. Animals were followed for four weeks (complete healing). DTIC

MAXIMUM TEAM LIFTING CAPACITY AS A FUNCTION OF TEAM SIZE

Marilyn A. Sharp, Valerie J. Rice, Bradley C. Nindl, and Tania L. Williamson Oct. 1993 70 p

(AD-A271642; USARIEM-T94-2) Avail: CASI HC A04/MF A01

The relationship between the sum of individual lifts and team lifting capacity in two-, three-, and four-person teams was examined. Twenty-three men and 17 women were assigned to single and mixed-gender teams of two, three, or four persons. A weight-lifting bar was used to measure individual deadlift, as square device for two- and four-person lifting and a triangular device for three-person lifting. Team lifting capacity increased with team size and with the number of males on the team. Team lifting capacity as a percent of the sum of deadlift strength (% sum) did not change with an increase in team size beyond two. The %sum for teams of men (87.3%) was less than for teams of women (91.1%, p less than .05), and the %sums for single gender teams were both greater (p less than .01) than for mixed-gender teams (80.2%). The limits for lift set by Military Standard 1472D (1989) are well below the capabilities demonstrated here, and there is ample evidence in the Military Occupational Classification Structure (1990) that soldiers are required to lift heavier loads than recommended. Since soldiers are capable of and required to lift more than the recommended loads, consideration could be given to increasing these design limits. DTIC

A GEOMETRICAL PROCESS FOR THREE DIMENSIONAL OSTEOTOMY PLANNING Ph.D. Thesis [GEOMETRISCHE VERFAHREN ZUR DREIDIMENSIONALEN OSTEOTOMIEPLANUNG]

Matthias Eck 1991 139 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ETN-93-93602) Avail: CASI HC A07

The possibilities of operation simulations with computer tomography before a bone operation are studied. An automatic algorithm was proposed for smoothing of digitalized datasets with an iterative formulation. Two algorithms are presented for data reduction, which are geometrical B-Spline curves and geometrical hermitian interpolation. Methods are described for bone surface reconstruction, which are based on Hardy multiquadrics. The well known implementation of experimental systems for planning of orthopedic operations were reviewed and two processes were developed in case of hip joint femur osteotomy, based on reconstructed computer tomography data, to estimate foreseeable member modifications before operations and to avoid or minimize them. RADIOMETRY IN COMMERCIAL AIRCRAFT Final Report [STRAHLENMESSUNGEN IN VERKEHRSFLUGZEUGEN. ABSCHLUSSBEREICHT]

D. Regulla and J. David Nov. 1991 88 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(GSF-41/91; ETN-93-93458) Copyright Avail: CASI HC A05

Cosmic radiation exposure of pilots, aircrew, and passengers during commercial flights is studied as a function of flight altitude and geographic latitude. Radiation measurements were carried out aboard the German Lufthansa airlines with a mobile measuring laboratory equipped with photon and neutron radiation measuring instruments. Several routes were considered to examine pole, equator, and geomagnetism effects. A scintillation dosimeter was used for electron and photon detection and a Rem-counter was employed for neutron identification. Because measuring instruments were not calibrated under high radiation conditions, a tissue equivalent proportional counter was available. It is concluded that radiation exposure increases with altitude and geographic and geomagnetic latitude. ESA

ENHANCEMENT OF WOUND HEALING BY BIOSYNTHETIC GROWTH FACTOR Midterm Report, 31 Jul. 1991 - 30 Jul. 1993

Gregory L. Brown and Gregory S. Schultz 30 Aug. 1993 147 p

(Contract DAMD17-91-C-1095)

(AD-A272517) Avail: CASI HC A07/MF A02

Our goal is to identify biological agents that play key roles in regulating normal healing, and using this knowledge, to develop methods to enhance wound healing. The major research focus has been centered on understanding the roles of peptide growth factors and proteases in normal wound healing. Fluids from healing human wounds contain extremely high levels of mitogenic activity; high levels of peptide growth factors including TGF-a, TGF-B, and IGF-I; and very low levels of proteolytic activity. In contrast, fluids from nonhealing ulcers contain low levels of mitogenic activity, low levels of growth factors, and very high levels of matrix metallo proteinases. Levels of EGF receptors also change during spontaneous healing of skin incisions. Thus, the molecular environment of healing wounds is radically different from the environment of chronic nonhealing wounds. We have utilized this knowledge to design rational combinations of growth factors and a new synthetic inhibitor of metallo proteinases (MMPI) that should improve healing of wounds. This combination of EGF and MMPI is undergoing testing in the pig skin graft model. If successful we will initiate a clinical trial with this formulation. We are also investigating TGF-B treatment to improve survival of irradiated skin flaps. DTIC

(AD-A272000) Avail: CASI HC A03/MF A01

For materials with possible use as wound coverings, control of the temperature of transition by changes in hydrophobicity will be examined. In addition, the rate of water passage through the matrix will be determined. The research approach is the stepwise coordination of the synthesis and characterization of the materials. The first application phase was concerned primarily with synthesis of the basic plypentapeptide poly(VPGVG) and the analog with L-alanine substituted in position 3, poly(VPAVG) and mole fraction combinations thereof to achieve elastomeric matrices of varying elastic moduli. And in the third year polypentapeptides containing chemical clocks are to be characterized for their rate of breakdown and their effects on drug release profiles. Derived from text

(NASA-TM-104782; S-742; NAS 1.15:104782) Avail: CASI HC A03/MF A01

The Johnson Space Center leads the research and development activities that address the health effects of space radiation exposure to astronaut crews. Increased knowledge of the composition of the environment and of the biological effects of space radiation is required to assess health risks to astronaut crews. The activities at the Johnson Space Center range from quantification of astronaut exposures to fundamental research into the biological effects resulting from exposure to high energy particle radiation. The Spaceflight Radiation Health Program seeks to balance the requirements for operational flexibility with the requirement to minimize crew radiation exposures. The components of the space radiation environment are characterized. Current and future radiation monitoring instrumentation is described. Radiation health risk activities are described for current Shuttle operations and for research development program activities to shape future analysis of health risk. Author

DEVELOPMENT OF THE UTC-PAB NORMATIVE DATABASE Final Report, Jun. 1990 - May 1992
Robert E. Schlegel, Kirby Gilliland, and Mark S. Crabtree Oct. 1992 284 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-88-D-0532)
(AD-A271319; AL-TR-1992-0145) Avail: CASI HC A13

This report summarizes the development of a comprehensive normative database for a large subset of tasks from the Unified Tri-Service Cognitive Performance Assessment Battery (UTC-PAB). Tasks were selected from the AGARD STRES, CTS, and Walter Reed batteries. Data were collected by the University of Oklahoma and Armstrong Laboratory. All data were analyzed at the University of Oklahoma to address issues related to task reliability, comparability of tasks across batteries, group vs. individual test administration, order of task presentation and battery sequence, test-retest time intervals, imposition of response deadlines, extended trial lengths, and the usefulness of psychometric state measures. With few exceptions, the data showed remarkable consistency across task batteries and within task types. Task reliability varied as a function of the dependent measure. CTS data showed good correspondence to a previous large-scale CTS database. Task presentation order and battery sequence did not influence task performance. Response deadlines provided a faster mean response time, but at the expense of more missed responses. Extended trial lengths had a more profound effect on continuous motor tasks such as Unstable Tracking. Changes in the psychometric state measures of sleepiness and mood were local reflections of time on task. DTIC

PHYSIOLOGICAL CORRELATES OF STRESS-INDUCED DECREMENTS IN HUMAN PERCEPTUAL PERFORMANCE Final Report
Garnet A. McLean (Federal Aviation Administration, Oklahoma City, OK.), Landgrave T. Smith, Timothy J. Hill, and Carl J. Rubenstein Nov. 1993 13 p
(Contract DAMD17-83-C-3194)
(DOT/FAA/AM-93/19) Avail: CASI HC A03/MF A01

Stress-induced changes in human performance have been thought to result from alterations in the 'multidimensional arousal state' of the individual, as indexed by alterations in the physiological and psychological mechanisms controlling performance. Identification of such changes in substrate activities provide more complete descriptions of both the performance changes and the arousal state/mechanisms. Decrements in perceptual performance were produced by independent and combined administration of atropine, sleep loss, and exercise for both a visual aircraft identification task and an auditory vigilance task; measurements of performance changes were accompanied by state measures of cardiovascular function, pupillary diameter, sleep onset latency, and subject self reports. Observed performance changes were accompanied by monotonic increases in heart rate after atropine and exercise, but not sleep loss. Moderate exercise produced blood pressure changes indicative of physical workload, but only atropine increased diastolic blood pressure and pupillary diameter relative to performance effects. Atropine and sleep loss each reduced sleep onset times to less than 50 percent control values (p is less than .0001); when combined with exercise, sleep onset times were reduced further (p is less than .03). These reductions in general arousal were confirmed by subject self-reports of reduced attentiveness and competence. These state measures of organismic function were found to be discriminatively correlative, but not predictive, of the decrements in perceptual performance seen; however, practical combinations of appropriate real-time measurement techniques could be developed that would promote the telemetering of human physiological activity to signal performance breakdown. INCONGRUITY, INCONGRUITY RESOLUTION, AND MENTAL STATES: THE MEASURE AND MODIFICATION OF SITUATIONAL AWARENESS AND CONTROL Final Report, 1 Jun. 1991 - 31 May 1993
Peter L. Derks and Lynn S. Gillikin 1 Jul. 1993 97 p
(Contract NCC1-160)
(NASA-CR-194568; NAS 1.26:194568) Avail: CASI HC A05/MF A02

The research reported here describes the process of induction of various mental states. Our goals were to measure and to manipulate both the behavioral and the neurological correlates of particular mental states that have previously been demonstrated to be either beneficial or deleterious to in-flight performance situations. The experimental paradigm involved developing a context of which the participants were aware, followed by the introduction of an incongruity into that context. The empirical questions involved how the incongruity was resolved and the consequent effects on mental state. The dependent variables were measures of both the short-term ERP changes and the longer-term brain mapping indications of predominant mental states. The mission of NASA Flight Management Division and Human/Automation Integration Branch centers on the understanding and improvement of interaction between a complex system and a human operator. Specifically, the goal is improved efficiency through better operative procedures and control strategies. More efficient performance in demanding

flight environments depends on improved situational awareness and replanning for fault management. Derived from text

COGNITION AND THE BRAIN: A CONTINUATION OF THE UNIVERSITY RESEARCH INITIATIVE AT NEW YORK UNIVERSITY Final Report, 15 Feb. 1990 - 14 Feb. 1993
Lloyd Kaufman 19 Oct. 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0221-90)
(AD-A271872; AFOSR-93-0818TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The main focus of this project was to make use of magneto-encephalographic (MEG) measures of brain activity to determine how the brain's neural resources are deployed during various cognitive tasks entailing different degrees of mental workload. Our laboratory pioneered this field, and the methods it devised are presently in wide use in clinical applications, as well as in other research laboratories. We initiated the use of a simple procedure to fit observed extracranial field patterns to fields that would be produced by equivalent current dipoles. The ideal dipole's position, orientation, and strength (current dipole moment) was adjusted until its field pattern matched that of the observed pattern. This is a primitive form of what we now refer to as Magnetic Source Imaging (MSI). It is still the basic method in clinical applications, but a more sophisticated form of MSI is now emerging, largely as a result of work on this project. DTIC

HEAD-CENTERED ORIENTATION STRATEGIES IN ANIMATE VISION
Enrico Grosso and Dana H. Ballard Oct. 1992 25 p
(Grant NIH-1R24RRO6853)
(TR-442) Avail: CASI HC A03/MF A01

This paper is about orienting, that is, establishing and maintaining a spatial relation between a motorized pair of cameras (the eye-head system) and a static or a moving object tracked over time. Motivated by physiological evidence, the paper proposes a simple set of vision-based strategies aimed to perform head, eyes and body movements in a complex environment. Fixation is shown to be an essential feature in visual servoing, and it is used to decouple control on head rotational degrees of freedom, making possible a metric-less approach to the orientation problem. A running implementation of these strategies, using a binocular camera system mounted on a PUMA 700, demonstrates the electiveness of the approach. Author

This document reports on work associated with the three-phase development of a psychologically-based human performance process model that can be used in the assessment of system performance. The first phase produced a preliminary architecture consisting of two parts: a 'mass memory' composed of long term memory structures that supported associative activation, and a set of sensory, perceptual, cognitive, and motor agents that communicated via message passing - writing messages to or reading messages from the mass. Phase two produced a revised architecture in which the distinction between memory and process disappeared and the resulting structures became active processing elements in a data flow structure. The addition to model development, certain activities associated with enroute air traffic control were also decomposed in order to develop the basis for a scenario within which to prototype, program, and test aspects of the revised model. The activities selected provided an opportunity to model single and multitasking behaviors and performance. DTIC

A DESCRIPTION OF PSYCHOLOGICAL TYPE AT THE DEFENSE SYSTEMS MANAGEMENT COLLEGE, 1993 EDITION
Carl Bryant, William H. Cummings, Daniel B. Chapla, Donald S. Fujii, and Mary-Jo Hall 1993 31 p
(AD-A271612) Avail: CASI HC A03/MF A01

This paper describes the psychological type, as measured by the Myers-Briggs Type Indicator, of a representative sample of more than 3,700 students who attended the Defense Systems Management College (DSMC) since 1985. This study addresses the contributions and potential pitfalls that personnel with each Myers-Briggs Type bring to an organization, and implications for leaders who must work in a possibly changing work force. This descriptive analysis may enable all who work in the defense acquisition environment to understand their coworkers better and, in this understanding, to enhance the overall acquisition process. PSYCHOMETRIC DEVELOPMENTS RELATED TO TESTS AND SELECTION
Bengt O. Muthen Aug. 1993 7 p
(Contract N00014-93-1-0619)
(AD-A272971) Avail: CASI HC A02/MF A01

Recent theoretical developments in the areas of latent variable modeling, random coefficient modeling, multilevel modeling, missing data theory, and empirical Bayes estimation provide interesting research opportunities for the psychometric modeling of the relationship between job performance and test performance. These developments suggest new approaches to the assessment of predictive validity of tests as well as to problems of selection and assignment. The purpose of the project is to use these theories as a basis for developing new psychometric methods that have the potential for better understanding the predictive validity of tests like the ASVAB and improving the selection and assignment of recruits for military jobs. EXTRACTING INFORMATION FROM WRONG ANSWERS IN COMPUTERIZED ADAPTIVE TESTING Final Report, Oct. 1988 - Sep. 1991
J. B. Sympson Oct. 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272832; NPRDC-TN-94-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A brief review of the history of polychotomous (i.e., multi-category) item response models is provided. After describing a new polychotomous item response model (Model 8), examples of the Operating Characteristic Functions obtained when Model 8 is applied to real test data are given. In general, inspection of 'goodness-of-fit' plots indicates that Model 8 provides superior data fit and higher item information functions than the well-known 3-parameter logistic (dichotomous) item response model. A simulation of computerized adaptive testing (CAT) that used the actual item responses of applicants for military enlistment shows that Model 8 would be superior to the 3-parameter logistic model in a CAT environment. In this investigation, Model 8 increased test reliability by an amount that is equivalent to a 25% increase in test length. DTIC

COMPATIBILITY EVALUATION AND RESEARCH ON THE COMPUTERIZED ADAPTIVE SCREENING TEST (CAST): USER AND PROGRAMMER'S GUIDE Final Report, Oct. 1989 - Jan. 1991
Randolph K. Park and Michael L. Dunn Oct. 1993 32 p
(Contract DAAL03-86-D-0001)
(AD-A273112; ARI-RN-94-01) Avail: CASI HC A03/MF A01

The Computerized Adaptive Screening Test (CAST) is used for predicting performance on the Armed Forces Qualification Test (AFQT). The goal of this project is to ensure CAST compatibility with the Electronic Information Delivery System (EIDS) now being fielded by the U.S. Army Recruiting Command. A number of software enhancements were implemented. Improvements were made in test item selection, reporting capability, experimental item selection, data storage capability, and software coordination. This report is a guide for users and programmers. THE EFFECTS OF INSTRUCTIONAL SETS ON REACTIONS TO AND PERFORMANCE ON AN INTELLIGENT TUTORING SYSTEM Final Technical Report
Debra Steele Johnson 20 Dec. 1993 50 p
(Grant NAG9-555)
(NASA-CR-194739; NAS 1.26:194739) Avail: CASI HC A03/MF A01

The effects of a contextual factor, i.e., task instructions, on performance on and reactions to an Intellegent Tutoring System (ITS) training Remote Manipulator System (RMS) tasks were examined. The results supported the first prediction that task instructions could be used to successfully induce a mastery versus an achievement orientation. Previous research suggests that a mastery orientation can result in beneficial effects on learning and performance of complex tasks. Furthermore, the results supported the second prediction that a mastery orientation would have beneficial effects on learning and performance as well as affective and cognitive reactions to the ITS tasks. Moreover, the results indicated that a mastery orientation was especially beneficial for the more complex ITS tasks and later in task practice, i.e., when a task was performed for the second time. A mastery orientation is posited to have its beneficial effects by focusing more effort and attention on task performance. Conclusions are drawn with some caution due to the small number of subjects, although the results for these subjects were consistent across multiple trials and multiple measures of performance. ITS designers are urged to consider contextual factors such as task instructions and feedback in terms of their potential to induce a mastery versus an achievement orientation.

NIGHT VISION GOGGLE MODEL F4949 PREFLIGHT ADJUSTMENT/ASSESSMENT PROCEDURES Final Report, Mar. - Jun. 1993
Joseph C. Antonio and William E. Berkley Aug. 1993 21 p
(Contract F33615-90-C-0005)
(AD-A271079; AL/HR-TR-1993-0111) Avail: CASI HC A03/MF A01

Night vision goggles (NVG's) have been employed in a variety of aircraft for over twenty years. However, only recently has their application begun in fixed-wing fast movers. Research accomplished by the Night Vision Programs Office at the Aircrew Training Research Division of the USAF Armstrong Laboratory demonstrated the loss of NVG performance resulting from improper adjustments. This report describes correct adjustment procedures for the F4949 NVG system. The procedures described were developed so aircrews could take advantage of the adjustments available on the NVG's. Additionally, image descriptions are given to help aircrews evaluate NVG performance. Information on the proper equipment/space needed for proper evaluation is also included. DTIC

SHIELDING FROM SPACE RADIATIONS Progress Report, 1 Jun. - 1 Dec. 1993
C. Ken Chang, Forooz F. Badavi, and Ram K. Tripathi 1 Dec. 1993 39 p
(Contract NCC1-178)
(NASA-CR-194683; NAS 1.26:194683) Avail: CASI HC A03/MF A01

This Progress Report covering the period of 1 June 1993 to 1 Dec. 1993 presents the development of an analytical solution to the heavy ion transport equation in terms of a one-layer Green's function formalism. The mathematical developments are recasted into an efficient computer code for space applications. The efficiency of this algorithm is accomplished by a nonperturbative technique of extending the Green's function over the solution domain. The code may also be applied to accelerator boundary conditions to allow code validation in laboratory experiments. Results from the isotopic version of the code with 80 isotopes present for a single layer target material, for the case of an iron beam projectile at 600 MeV/nucleon in water is presented. QUINOA: AN EMERGING NEW CROP WITH POTENTIAL FOR CELSS
Greg Schlick and David L. Bubenheim Nov. 1993 9 p
(RTOP 199-61-12-28)
(NASA-TP-3422; A-93100; NAS 1.60:3422) Avail: CASI HC A02/MF A01

Chenopodium quinoa is being considered as a new crop for the Controlled Ecological Life Support System (CELSS) because of its high protein values (12 - 18%) and unique amino acid composition. Lysine, and essential amino acid that is deficient in many grain crops, is found in quinoa approaching Food and Agriculture Organization of the United Nations (FAO) standards set for humans. This 'new' crop, rich in protein and with desirable proportions of important amino acids, may provide greater versatility in meeting the needs of humans on long-term space missions. Initially, the cultivars CO407 x ISLUGA, CO407 Heat Tolerant Population 1, and Real' (a Bolivian variety) were examined. The first cultivar showed the most promise in greenhouse studies. When grown hydroponically in the greenhouse, with no attempt to maximize productivity, this cultivar produced 202 g m(exp -2) with a harvest index of 37%. None of the cultivars were greater than 70 cm in height. Initial results indicate that quinoa could be an excellent crop for CELSS because of the high concentration of protein, ease of use, versatility in preparation, and potential for greatly increased yields in controlled environments. Method and apparatus for accurately simulating locomotion in a weightless environment, especially to prevent atrophy of a subject's musculoskeletal and cardiorespiratory systems during space travel, are disclosed. Forces, including the vertical, horizontal, and lateral force generated by an individual during locomotion on a treadmill using a rigid belt with rigid transfer elements supported by low friction bogies, are measured by strain gauges sensitive in their respective direction. The vertical forces produced by securing the subject to the treadmill via bungee cords, in conjunction with the measured velocity of the treadmill and the mode of locomotion, are used to determine the subject's equivalent weight. The other horizontal and lateral forces are used to determine the external work produced by the subject when locomotion is performed on a nonlevel surface with an effective grade angle. The measured forces are related in such a way that the grade angle is easily determined. A motor and additional circuitry can be added to the apparatus to measure and force a subject to maintain a predetermined work rate associated with a preselected grade angle and tread velocity.

COSMOS 2229 Final Report
V. Reggie Edgerton, Roland R. Roy, and John A. Hodgson Nov. 1993 17 p
(Contract NCC2-535; Proj. K-7-33)
(NASA-CR-194734; NAS 1.26:194734) Avail: CASI HC A03/MF A01

The 6 weeks preflight activities of the Cosmos project during 1993 included: modification of EMG connector to improve the reliability of EMG recording; 24 hour cage activity recording from all but two of the flight animals (monkeys); attempts to record from flight candidates during foot lever task; and force transducer calibrations on all flight candidate animals. The 4 week postflight recordings included: postflight recordings from flight

animals; postflight recordings on 3 control (non-flight) animals; postflight recalibration of force transducers on 1 flight and 4 control (non-flight) animals; and attempts to record EMG and video data from the flight animals during postflight locomotion and postural activity. The flight EMG recordings suggest that significant changes in muscle control may occur in spaceflight. It is also clear from recordings that levels of EMG recorded during spaceflight can attain values similar to those measured on earth. Amplifier gain settings should therefore probably not be changed for spaceflight. Derived from text

AUTOMATIC LOCKING ORTHOTIC KNEE DEVICE Patent

Bruce C. Weddendorf, inventor (to NASA) 7 Dec. 1993 8 p Filed 26 Dec. 1991 Supersedes N92-17866 (30 - 8, p 1335)

(NASA-Case-MFS-28633-1; US-Patent-5,267,950; US-Patent-Appl-SN-813629; US-Patent-Class-602-26; US-Patent-Class-602-16; US-Patent-Class-623-43; US-Patent-Class-623-44; Int-Patent-Class-A61F-5/00) Avail: US Patent and Trademark Office

An articulated tang in clevis joint for incorporation in newly manufactured conventional strap-on orthotic knee devices or for replacing such joints in conventional strap-on orthotic knee devices is discussed. The instant tang in clevis joint allows the user the freedom to extend and bend the knee normally when no load (weight) is applied to the knee and to automatically lock the knee when the user transfers weight to the knee, thus preventing a damaged knee from bending uncontrollably when weight is applied to the knee. The tang in clevis joint of the present invention includes first and second clevis plates, a tang assembly and a spacer plate secured between the clevis plates. Each clevis plate includes a bevelled serrated upper section. A bevelled shoe is secured to the tank in close proximity to the bevelled serrated upper section of the clevis plates. A coiled spring mounted within an oblong bore of the tang normally urges the shoes secured to the tang out of engagement with the serrated upper section of each clevic plate to allow rotation of the tang relative to the clevis plate. When weight is applied to the joint, the load compresses the coiled spring, the serrations on each clevis plate dig into the bevelled shoes secured to the tang to prevent relative movement between the tang and clevis plates. A shoulder is provided on the tang and the spacer plate to prevent overextension of the joint.

LOADS PRODUCED BY A SUITED SUBJECT PERFORMING TOOL TASKS WITHOUT THE USE OF FOOT RESTRAINTS

Sudhakar L. Rajulu (Lockheed Engineering and Sciences Co., Houston, TX.), Jeffrey Poliner (Lockheed Engineering and Sciences Co., Houston, TX.), and Glenn K. Klute Dec. 1993 38 p

(Contract NAS9-17900)

(NASA-TP-3424; S-744; NAS 1.60:3424) Avail: CASI HC A03/MF A01

With an increase in the frequency of extravehicular activities (EVA's) aboard the Space Shuttle, NASA is interested in determining the capabilities of suited astronauts while performing manual tasks during an EVA, in particular the situations in which portable foot restraints are not used to stabilize the astronauts. Efforts were made to document the forces that are transmitted to spacecraft while pushing and pulling an object as well as while operating a standard wrench and an automatic power tool. The six subjects studied aboard the KC-135 reduced gravity aircraft were asked to exert a maximum torque and to maintain a constant level of torque with a wrench, to push and pull an EVA handrail, and to operate a Hubble Space Telescope (HST) power tool. The results give an estimate of the forces and moments that an operator will transmit to the handrail as well as to the supporting structure. In general, it was more effective to use the tool inwardly toward the body rather than away from the body. There were no differences in terms of strength capabilities between right and left hands. The power tool was difficult to use. It is suggested that ergonomic redesigning of the power tool may increase the efficiency of power tool use. Author (revised)

SYSTEM TEST RESULTS OF THE ADVANCED TECHNOLOGY ANTI-G SUIT (ATAGS) Final Report, Oct. 1991 - Nov. 1992

Larry J. Meeker, John H. Olhausen, and Grady L. Ripley Nov. 1992 10 p

(AF Proj. 2830)

(AD-A271535; AL/CF-TP-1993-0033) Avail: CASI HC A02/MF A01

Previous centrifuge and flight testing have shown that the ATAGS offers superior G endurance protection even when operated at lower pressures than the standard anti-G suit. All of the previous ATAGS testing was done, however, using human test subjects for the purpose of evaluating G protection. The purpose of the parametric tests was to provide basic system data such as volumes, fill rates and pressure differentials for the ATAGS. In order to allow direct comparison with data taken previously on the AF standard anti-G suit (CSU-13A/P), these tests were based on procedures detailed in SAM-TR-78-12, Engineering Test, and Evaluation During High G, VOL III: Anti-G Suits. ATAGS volumes were measured using pressure change during expansion from a known volume. The volumes of several suit sizes were taken, both with the suit unmounted and mounted on a mannequin to a proper fit. Total flow was measured with a flowmeter in the main fill hose. Differential pressure in various parts of the suit during rapid fill was measured at test points located on both sides of the abdominal bladder, on each thigh, and at the bottom of each leg. Preliminary data from these tests are presented. DTIC

IN-FLIGHT MEASUREMENT OF AIRCREW BREATHING IN NAVY AIRCRAFT

Dennis N. Gordge 20 Sep. 1993 74 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A271811; NAWCADPAX-TM-93-59-SY) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A man-mounted, aircraft independent, self-contained recording system was developed for measuring the breathing flow rates of aircrew during all phases of flight. Breathing data of 41 Navy and Marine Corps aircrew operating F-14, F/A-18, A-7, A-6, and S-3 aircraft were measured during 51 flights including fleet combat exercises. The data were collected to validate current test and evaluation techniques and to modify oxygen system design and installation specifications. The data may also be used for designing future oxygen systems. The data generally show good correlation with previous studies, but also provide unique results for carrier operations and aerial combat maneuvering (ACM) conditions not previously reported. The results indicate that the current military oxygen system flow rate specifications are inadequate for tactical aircraft performing ACM. The results also suggest that current F-14 and F/A-18 oxygen systems may be inadequate for low altitude ACM. DTIC

N94-21247# Aerospace Medical Div., Brooks AFB, TX.

PHYSIOLOGICAL EFFICACY OF A LIGHTWEIGHT AMBIENT AIR COOLING UNIT FOR VARIOUS APPLICATIONS Final Report, Oct. 1988 - Sep. 1991

Yasu T. Chen, Susan H. Bomalaski, and Stefan H. Constable Oct. 1993 18 p

(AF Proj. 2729)

(AD-A272952; AL-TP-1993-0013) Avail: CASI HC A03/MF A01

In an attempt to further advance intermittent conditioned air cooling (IC) concept, a strategy of supplementing continuous air cooling (CC) was conceived. With this approach, ambient air cooling (AC) is added during work with conditioned air cooling delivered during rest periods. A compact, battery-powered belt-pack cooling unit (8.5 lb), designed and fabricated at the USAF Armstrong Laboratory, was used to deliver 12 cfm filtered ambient air during work cycles: 10 cfm to the body and 2 cfm to the face. Five experimental trials were completed in a thermally controlled chamber under warm conditions (32 deg C, 40% RH) consisting of no cooling (NC), IC, and CC during intermittent exercise, as well as NC and AC during continuous exercise. This study suggests that ambient air delivered during work by a lightweight portable unit can be applied in conjunction with conditioned air during rest to further improve personal comfort, reduce skin temperature, and decrease the cumulative fatigue seen over repeated work/rest cycles in selected military and industrial applications. A generic examination of the loads produced by individuals performing maximal efforts with a torquing tool in zero gravity, to determine operator strength when performing torquing tasks; quantify the loads placed on foot restraints while performing these tasks; and examine effects of orientation and direction of tool rotation on strength effectiveness was conducted. The experiment was conducted aboard NASA's KC-135 reduced-gravity aircraft, using two force plates attached to a test stand, one with a foot restraint. Subjects used a wrench to apply maximum torques to various fittings, in different positions, in clockwise and counterclockwise directions. It was seen that these subjects could produce approximately 400 to 750 N of force, depending on the orientation of the tool and the direction of effort. The most force could be produced when pushing the tool upwards. A force effectiveness ratio (FER) defined as an indication of how much of the subjects' total effort actually went into performing the desired task. Values of FER ranged from 0.55 to 0.90, with the greatest FER occurring with UP and DOWN efforts, and the lowest with AWAY and LEFT efforts. Designers can use these results to set specifications for craft structures; tools can be developed based on the known strength of the tool users; and tasks can be developed to not exceed the crewmembers' capabilities. EVA TOOLS AND EQUIPMENT REFERENCE BOOK
R. K. Fullerton Nov. 1993 737 p Revised
(NASA-TM-109350; NAS 1.15:109350; JSC-20466-Rev-B) Avail: CASI HC A99/MF A06

This document contains a mixture of tools and equipment used throughout the space shuttle-based extravehicular activity (EVA) program. Promising items which have reached the prototype stage of development are also included, but should not be considered certified ready for flight. Each item is described with a photo, a written discussion, technical specifications, dimensional drawings, and points of contact for additional information. Numbers on the upper left-hand corner of each photo may be used to order specific pictures from NASA and contractor photo libraries. Points of contact were classified as either operational or technical. An operational contact is an engineer from JSC Mission Operations Directorate who is familiar with the basic function and on-orbit use of the tool. A technical contact would be the best source of detailed technical specifications and is typically the NASA subsystem manager. The technical information table for each item uses the following terms to describe the availability or status of each hardware item: Standard - Flown on every mission as standard manifest; Flight specific - Potentially available for flight, not flown every mission (flight certification cannot be guaranteed and recertification may be required); Reference only - Item no longer in active inventory or not recommended for future use, some items may be too application-specific for general use; and Developmental - In the prototype stage only and not yet available for flight. The current availability and certification of any flight-specific tool should be verified with the technical point of contact. Those tools built and fit checked for Hubble Space Telescope maintenance are program dedicated and are not available to other customers. Other customers may have identical tools built from the existing, already certified designs as an optional service. Author (revised)

A third antenna was added to the system. It is a terrestrial low-gain feed, to act as a veto for local interference. The 3-chip design for a 4 megapoint complex FFT was reduced to finished working hardware. The 4-Megachannel circuit board contains 36 MByte of DRAM, 5 CPLDs, the three large FFT ASICs, and 74 ICs in all. The Austek FDP-based Spectrometer/Power Accumulator (SPA) has now been implemented as a 4-layer printed circuit. A PC interface board has been designed and together with its associated user interface and control software allows an IBM compatible computer to control the SPA board, and facilitates the transfer of spectra to the PC for display, processing, and storage. The Feature Recognizer Array cards receive the stream of modulus words from the 4M FFT cards, and forward a greatly thinned set of reports to the PC's in whose backplane they reside. In particular, a powerful ROM-based state-machine architecture has been adopted, and DRAM has been added to permit integration modes when tracking or reobserving source candidates. The general purpose (GP) array consists of twenty '486 PC class computers, each of which receives and processes the data from a feature extractor/correlator board set. The array performs a first analysis on the provided 'features' and then passes this information on to the workstation. The core workstation software is now written. That is, the communication channels between the user interface, the backend monitor program and the PC's have working software. Derived from text

HIGHER ORDER BEZIER CIRCLES
Jin Chou Dec. 1993 20 p
(Contract NAS2-12961)

(NASA-CR-177633; A-94040; NAS 1.26:177633) Avail: CASI HC A03/MF A01

Rational Bezier and B-spline representations of circles have been heavily publicized. However, all the literature assumes the rational Bezier segments in the homogeneous space are both planar and (equivalent to) quadratic. This creates the illusion that circles can only be achieved by planar and quadratic curves. Circles that are formed by higher order rational Bezier curves which are nonplanar in the homogeneous space are shown. The problem of whether it is possible to represent a complete circle with one Bezier curve is investigated. In addition, some other interesting properties of cubic Bezier arcs are discussed. A PARALLELIZING COMPILER BASED ON PARTIAL EVALUATION

Rajeev Surati Jul. 1993 55 p

(Contract N00014-92-J-4097)

(AD-A270838; AI-TR-1377) Avail: CASI HC A04/MF A01

This thesis demonstrates a compiler that uses partial evaluation to achieve outstandingly efficient parallel object code from very high-level source programs. The source programs are ordinary Scheme numerical programs, written abstractly, with no attempt to structure them for parallel execution. The compiler identifies and extracts parallelism completely automatically; nevertheless, it achieved by speed-ups equivalent to or better than the best observed results achieved by previous supercomputer compilers that require manual restructuring of code. REFERENCE MANUAL FOR A REQUIREMENTS SPECIFICATION LANGUAGE (RSL), VERSION 2.0

Gene L. Fisher and Gerald C. Cohen (Boeing Defense and Space Group, Seattle, WA.) Nov. 1993 30 p

(Contract NAS1-18586; RTOP 505-64-10-07)

(NASA-CR-191460; NAS 1.26:191460) Avail: CASI HC A03/MF A01

This report is a Reference Manual for a general-purpose Requirements Specification Language, RSL. The purpose of RSL is to specify precisely the external structure of a mechanized system and to define requirements that the system must meet. A system can be comprised of a mixture of hardware, software, and human processing elements. RSL is a hybrid of features found in several popular requirements specification languages and includes constructs for formal mathematical specification. Author (revised)

NOMINALIZATION, PREDICTION AND TYPE CONTAINMENT

F. Kamareddine (Glasgow Univ., Scotland.) and E. Klein (Edinburgh Univ., Scotland.) 1992 51 p Prepared in cooperation with Glasgow Univ. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-191799; COMPUTING SCIENCE NOTES-92/23) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Type disciplines have featured prominently in formal approaches to natural language. The paper examines type-free theories of properties in order to accommodate the difficulties raised by nominalization and self-application. Historically, type disciplines for languages have developed in close association with intended models for interpretation. The proposals the authors shall make can also be construed in this way, inasmuch as they were inspired in part by the notion of a Frege structure, which is intended to provide a consistent formulation of Frege's logical notion of set. A system of types provides a classificatory scheme for the domain and range of functors. The type of an expression determines the domain in which that expression receives an interpretation. NTIS

(AD-A270550; CMU-CS-93-190) Avail: CASI HC A16

Microprocessors are now ubiquitous, but their design is not without difficulties. Numerous microprocessors have been introduced only to find--sometimes years later--that they contain mistakes. The need for better ways of checking designs is clear. This research develops a methodology for formally verifying data-intensive circuits against abstract state machines defined by assertions and applies it to show that a microprocessor circuit implements its intended instruction set. 'Implementation' is a formal relation between input-output sequences: of an abstract state machine, and of a circuit. This simple abstract model of behavior is reconciled with concepts from digital-systems design including dynamic logic, pipelining, multi-phase clocks, and a separate memory system. The methodology structures proof of implementation using a series of decompositions. It exposes the internal system state. It dissects sequences into their component transitions (using a new formalism called marked strings to reason about overlapped operation). For processor verification it also abstracts away most of the memory state. DTIC

LIGHTWEIGHT RECOVERABLE VIRTUAL MEMORY

M. Satyanarayanan, Henry H. Mashburn, Puneet Kumar, David C. Steere, and James J. Kistler Aug. 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F33615-90-C-1465; ARPA Order 7597)

(AD-A270576; CMU-CS-93-143) Avail: CASI HC A03

Recoverable virtual memory refers to regions of a virtual address spare on which transactional guarantees are offered. This paper describes RVM, an efficient, portable, and easily used implementation of recoverable virtual memory for UNIX environments. A unique characteristic of RVM is that it allows independent control over the transactional properties of atomicity, permanence, and serializability. This leads to considerable flexibility in the use of RVM, potentially enlarging the range of applications than can benefit from transactions. It also simplifies the layering of functionality such as nesting and distribution. The paper shows that RVM performs well over its intended range of usage even though it does not benefit from specialized operating system support. It also demonstrates the importance of intra- and inter-transaction optimizations. DTIC

M-DIMENSIONAL COMPUTER MEMORY WITH M-1 DIMENSIONAL HYPERPLANE ACCESS Patent

Allen D. Parks, inventor (to Navy), James C. Perry, inventor (to Navy), and

Albert P. Shuler, inventor (to Navy) 21 Sep. 1993 7 p Filed 9 Jul. 1990 Supersedes AD-D014615
(AD-D015960; US-Patent-5,247,630; US-Patent-Appl-SN-551103; US-Patent-Class-395-400) Avail: US Patent and Trademark Office

An m-dimensional memory with m-1 dimensional hyperplane access. Random access memory (RAM) circuits are arranged in a plurality of groups for storing data words corresponding to vertices of an m-dimensional lattice. Each vertex of the lattice is defined by an m-tuple. The minimum number of RAM circuits required to realize the memory architecture of the present invention is based upon the size of the lattice and the distribution of the data words in memory is based upon the m-tuples used to define the lattice. DELIVERY OF VERY HIGH BANDWIDTH WITH ATM SWITCHES AND SONET
S. A. Gossage 1993 9 p Presented at the 29th Annual International Telemetering Conference, Las Vegas, NV, 25-28 Oct. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019432; SAND-93-1686C; CONF-9310131-2) Avail: CASI HC A02/MF A01

To deliver high bandwidth, a ubiquitous inter-/intra-building cable plant consisting of single mode and multimode fiber as well as twisted pair copper is required. The selection of the 'glue' to transport and interconnect distributed LAN's with central facility resources over a pervasive cable plant is the focus of this paper. A description of the traditional problems that must be overcome to provide very high bandwidth beyond the narrow confines of a computer center is given. The applicability of Asynchronous Transfer Mode (ATM) switching (interconnection) and Synchronous Optical NETwork (SONET) (transport) for high bandwidth delivery is described using the environment and requirements of Sandia National Laboratories. Other methods for distributing high data rates are compared and contrasted. Sandia is implementing a standards based foundation utilizing a pervasive single mode fiber cable plant, SONET transport, and ATM switching to meet the goals of gigabit networking. DOE

TIME WARP OPERATING SYSTEM VERSION 2.7 INTERNALS MANUAL
Feb. 1992 233 p
(Contract NAS7-918)
(NASA-CR-194798; JPL-D-9516; NAS 1.26:194798; AD-A271489) Avail: CASI HC A11/MF A03

The Time Warp Operating System (TWOS) is an implementation of the Time Warp synchronization method proposed by David Jefferson. In addition, it serves as an actual platform for running discrete event simulations. The code comprising TWOS can be divided into several different sections. TWOS typically relies on an existing operating system to furnish some very basic services. This existing operating system is referred to as the Base OS. The existing operating system varies depending on the hardware TWOS is running on. It is Unix on the Sun workstations, Chrysalis or Mach on the Butterfly, and Mercury on the Mark 3 Hypercube. The base OS could be an entirely new operating system, written to meet the special needs of TWOS, but, to this point, existing systems have been used instead. The base OS's used for TWOS on various platforms are not discussed in detail in this manual, as they are well covered in their own manuals. Appendix G discusses the interface between one such OS, Mach, and TWOS. DTIC

THE EFFECTS OF BLOCK SIZE ON THE PERFORMANCE OF COHERENT CACHES IN SHARED-MEMORY MULTIPROCESSORS Technical Report
Cezary Dubnicki May 1993 121 p
(Contract N00014-92-J-1801)
(AD-A272838; TR-462-ONR) Avail: CASI HC A06/MF A02

Several studies have shown that the performance of coherent caches depends on the relationship between the cache block size and the granularity of sharing and locality exhibited by the program. Large cache blocks exploit processor and spatial locality, but may cause unnecessary cache invalidations due to false sharing. Small cache blocks can reduce the number of cache invalidation, but increase the number of bus or network transactions required to load data into the cache. We use reference traces from a variety of parallel programs and detailed simulation of a scalable shared-memory multiprocessor to examine the effects of cache block size on the performance of coherent caches and quantify this impact with respect to the network bandwidth and latency. Our results suggest that, regardless of the available bandwidth or latency, applications with good spatial locality favor long cache lines, and for these applications the relative benefits of longer cache lines increase with the bandwidth and latency. DTIC

FAULT TOLERANT REAL-TIME SYSTEMS Annual Report, 1 Oct. 1992 - 30 Sep. 1993
John P. Lehoczky 30 Sep. 1993 12 p
(Contract N00014-92-J-1771)
(AD-A272878) Avail: CASI HC A03/MF A01

Over the last year, substantial progress was made on the integration of real-time scheduling with fault tolerance to create a theory of temporal redundancy. Temporal redundancy is an approach to real-time system dependability in which subtasks which are a part of tasks with real-time requirements but which fail their acceptance test can be executed again, the latter execution being scheduled so that, if successful, the task will meet its timing requirements, and the re-execution does not cause any other task to miss its deadline. The failures occur randomly, thus they create, in effect, a stream of periodic job requests. The job requests correspond to the time required to retry the subtask, or an alternative version of the subtask, and they have a deadline which is the same as the deadline of the failed task. The temporal redundancy problem, therefore, can be considered to be a special version of the problem of jointly scheduling hard deadline periodic tasks and aperiodic tasks. However, in this case, the aperiodic tasks also have hard deadlines, a problem which has never been addressed in the rate monotonic environment. The goal of this research is to develop methods to solve this new joint scheduling problem and to assess the efficacy of the algorithms produced in enhancing real-time system fault tolerance. This project is designed to study a new approach to software fault tolerance called analytic redundancy. It has been widely acknowledged that software failures are the most important issue in large computer system reliability. The failure rate of software has risen to 9.4 times the failure rate of hardware, and software failures have captured substantial media attention in recent years. The problem of software reliability is especially difficult, because the major recognized approaches (recovery blocks and n-version programming) are known to have serious drawbacks, and do not protect against whole classes of errors such as specification or design errors. SECURITY MANAGEMENT OF ELECTRONIC DATA INTERCHANGE

M.S. Thesis
Hua-Fu Pao Jun. 1993 139 p
(AD-A272962) Avail: CASI HC A07/MF A02

This thesis considers the security management issue of electronic data interchange (EDI) and the security tools that are used for secure EDI implementation. Management considerations of EDI are considered to be an integration of EDI and security services. The background of EDI is surveyed along with EDI implementation procedures and digital signature (DS) techniques. The security services that are being used today are discussed including the EDI-related security standards. Finally, a security management model is presented that may be used to improve the security of an EDI implementation. The model is based on the perceived threats and vulnerabilities to the EDI, and the availability of security services and mechanisms. Included in the model are the setting of security goals, the determination of security policies, the determination of priorities for EDI security, and the construction of security architecture and management activities. This thesis was written to survey the concepts of EDI and DS. The survey of EDI related security standards may provide an opportunity to understand security services and security mechanisms available when designing an EDI system. Also, the security management model may help to improve the security of an organization. DTIC

SPACE-EFFICIENT DETERMINISTIC SIMULATION OF PROBABILISTIC AUTOMATA
Ioan I. Macarie Jul. 1993 19 p
(Grant NSF CDA-88-22724)
(TR-463) Avail: CASI HC A03/MF A01

Given a description of a probabilistic automaton (one-head probabilistic finite automaton or probabilistic Turing machine) and an input string x of length n, we ask how much space does a deterministic Turing machine need in order to decide the acceptance of an input string by that automaton? The question is interesting even in the case of one-head one-way probabilistic finite automata. We call (rational) stochastic languages (S(sup greater than)(sub rat)) the class of languages recognized by these devices with rational transition probabilities and rational cutpoint. The class S(sup greater than)(sub rat) contains context-sensitive languages that are not context free, but on the other hand there are context-free languages not included in S(sup greater than)(sub rat). Our main results are as follows: (1) The (proper) inclusion of S(sup greater than)(sub rat) in Dspace(log n), which is optimal. The previous upper bounds were Dspace(n), and, in a special case, Dspace(log n loglog n). (2) The inclusion of the languages recognized by S(n) belonging to o(loglog log n) space-bounded probabilistic Turing machines in Dspace(2(exp S(n))log n). The previous upper bound was Dspace(log n(S(n)+log log n)). (Note that this improvement is meaningful, based on Freivalds' result that probabilistic Turing machines do not have a space complexity gap below loglog n like their deterministic and nondeterministic counterparts) . We present a technique to compare numbers given in terms of their values modulo a sequence of primes, 3 less than or equal to (LE) p(sub 1) LE p(sub 2) LE ... LE p(sub n) = O(n(exp a)) (where a is some constant) in O(log n) deterministic space. The previous result was O(log n loglog n). Author

DECOUPLED COMPUTER ARCHITECTURES FOR VERY HIGH-SPEED TECHNOLOGIES Final Report, 1 Jul. 1988 - 30 Jun. 1992
Steven E. Butner and Stephen I. Long Oct. 1993 56 p
(ARPA Order 6356)
(AD-A271646; ECE-93-19) Avail: CASI HC A04/MF A01

The long-term goal of this project is to develop the capability to apply and effectively use emerging high-speed integrated circuit (IC) technologies such as gallium-arsenide. Success in this endeavor requires experience with circuits, packaging, and architecture, not only in the new technologies, but also in current MOS IC technologies. The fundamental problem addressed is that though GaAs systems can now (or soon) quite readily be built with 100-150 MHz clock rates, the scaling beyond that speed is greatly complicated due to two effects: (1) some subsystems within a computer can support faster clock rates without much special consideration, but there are subsystems (most notably memory and communications) that cannot readily be made to follow the faster clock rates; and (2) conventional computer architecture is not capable of effectively dealing with high latency operations. As clock rates for some (but not all) of the subsystems of a computer increase, the relative latency of the remaining subsystems grows. DTIC

INTRODUCTION TO THE LARC CENTRAL SCIENTIFIC COMPUTING COMPLEX
John N. Shoosmith Nov. 1993 55 p Revised
(RTOP 505-60-01-01)
(NASA-TM-104092-Rev-1; NAS 1.15:104092-Rev-1) Avail: CASI HC A04/MF A01

The computers and associated equipment that make up the Central Scientific Computing Complex of the Langley Research Center are briefly described. The electronic networks that provide access to the various components of the complex and a number of areas that can be used by Langley and contractors staff for special applications (scientific visualization, image processing, software engineering, and grid generation) are also described. Flight simulation facilities that use the central computers are described. Management of the complex, procedures for its use, and available services and resources are discussed. This document is intended for new users of the complex, for current users who wish to keep appraised of changes, and for visitors who need to understand the role of central scientific computers at Langley. SOME TOPICS IN REGENERATIVE STEADY-STATE SIMULATION
Peter W. Glynn May 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0101)
(AD-A271145; SU-TR-93-5; ARO-29412.2-MA-SDI) Avail: CASI HC A03

This paper offers a short introduction to the regenerative method of steady-state simulation output analysis. The paper also contains several new results. In particular, it is shown that regenerative methods necessarily apply to steady-state simulations that are 'well-posed' in a certain precise sense. The paper also describes a bias-reduction algorithm that takes advantage of regenerative structure. DTIC

PLANNING PROCESS SOFTWARE: A USER GUIDE FOR THE DMCA
J. Clothier and J. ONeill Aug. 1993 202 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271252; ERL-0718-GD; DODA-AR-008-469) Avail: CASI HC A10

The Planning Process Software user guide was produced as supporting documentation to the element of the Operational Movements Planning System prototype addressing preference and constraint definition and tracking allocation of items to be moved to available transport assets. The User Guide was designed as an easy to use supplement to the Planning Process Software. For each user-computer interface in the software, a graphical display is shown. This is accompanied by a description of how the interface operates, what function is performed by the underlying software, and how the interface can be reached from elsewhere within the Software. A COMPARISON OF DATA-PARALLEL ALGORITHMS FOR CONNECTED COMPONENTS
John Greiner 18 Aug. 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-91-C-0168; ARPA Order 8313)
(AD-A270551; CMU-CS-93-191) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper presents a pragmatic comparison of three parallel algorithms for finding connected components. Those being compared are two similar algorithms by Awerbuch and Shiloach and by Shiloach and Vishkin and a randomized contraction algorithm by Blelloch, based on algorithms by Reif and Phillips. Major improvements are given for the first two which significantly reduces the super-linear component of their work complexity. An improvement is also given for the randomized algorithm, and this algorithm is shown to be the fastest of those tested. These comparisons are presented with NESL data-parallel code as executed on a Connection Machine 2. DTIC

(Contract F33615-90-C-1465; ARPA Order 7597)
(AD-A270552; CMU-CS-93-178) Avail: CASI HC A10

Because of the difficulty of adequately simulating large digital designs, there has been a recent surge of interest in formal verification, in which a mathematical model of the design is proved to satisfy a precise specification. Model checking is one formal verification technique. It consists of checking that a finite-state model of the design satisfies a specification given in temporal logic, which is a logic that can express properties involving the sequencing of events in time. One of the main drawbacks of model checking is the state explosion problem. This problem occurs in systems composed of multiple processes executing in parallel; the size of the state space generally grows exponentially with the number of components. This thesis considers two methods for avoiding the state explosion problem in the context of model checking: compositional verification and abstraction. DTIC

AN INTRODUCTION TO GUGA IN THE COLUMBUS PROGRAM SYSTEM
R. Shepard 1992 7 p Presented at the Relativistic and Electron Correlation Effects in Molecules and Solids, Vancouver, Ontario, 9-22 Aug. 1992
(Contract W-31-109-eng-38)
(DE93-018994; ANL/CHM/CP-80472; CONF-9208237-1) Avail: CASI HC A02/MF A01

The COLUMBUS Program System is a collection of FORTRAN programs for performing general multiconfiguration self-consistent-field (MCSCF) and multireference single- and double-exicitation configuration interaction (MRSDCI) wave function optimization based on the graphical unitary group approach (GUGA). This paper describes at an introductory level how wave functions are specified and characterized in the COLUMBUS Program System in terms of the unitary group, and in particular, using the graphical representation proposed by Shavitt. IMPLEMENTATION OF A PORTABLE NESTED DATA-PARALLEL LANGUAGE
Guy E. Blelloch, Siddhartha Chatterjee, Jonathan C. Hardwick, Jay Sipelstein, and Marco Zagha Feb. 1993 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-90-C-1465; ARPA Order 7597)
(AD-A270524; CMU-CS-93-112) Avail: CASI HC A03

This paper gives an overview of the implementation of NESL, a portable nested data-parallel language. This language and its implementation are the first to fully support nested data structures as well as nested data-parallel function calls. These features allow the concise description of parallel algorithms on irregular data structures, such as sparse matrices and graphs. In addition, they maintain the advantages of data-parallel languages: a simple programming model and portability. The current NESL implementation is based on an intermediate language called VCODE and a library of vector routines called CVL. It runs on the Connection Machines CM-2 and CM-5, the Cray C90, and serial workstations. We compare initial benchmark results of NESL with those of machine-specific code on these machines for three algorithms: least-squares line-fitting, median finding, and a sparse-matrix vector product. These results show that NESL's performance is competitive with that of machine-specific code for regular dense data, and is often superior for irregular data. DTIC

SET BASED ANALYSIS OF ML PROGRAMS
Nevin Heintze Jul. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-91-C-0168; ARPA Order 8313)
(AD-A270597; CMU-CS-93-193) Avail: CASI HC A03

Reasoning about a program by treating program variables as sets of values leads to a simple, accurate, and intuitively appealing notion of program approximation. This paper presents such an approach for the

compile-time analysis of ML programs. To develop the core ideas of the analysis, we consider a simple untyped call-by-value functional language. Starting with an operational semantics for the language, we develop an approximate set based operational semantics which formalizes the intuition of treating program variables as sets. The key result of the paper is an O(n3) algorithm for computing the set based approximation of a program. We then show how the analysis can be extended in a natural way to deal with arrays, arithmetic, exceptions, and continuations. We also briefly describe results from an implementation of this analysis for ML programs. DTIC

GLOBAL COMBINE ON MESH ARCHITECTURES WITH WORMHOLE ROUTING
M. Barnett, R. Littlefield, D. G. Payne, and R. vandeGeijn Apr. 1993 8 p Presented at the 7th International Parallel Processing Symposium, Newport Beach, CA, 13-16 Apr. 1993
(Contract DE-AC06-76RL-01830)
(DE93-018792; PNL-SA-22002; CONF-9304200-1) Avail: CASI HC A02/MF A01

Several algorithms are discussed for implementing global combine (summation) on distributed memory computers using a two-dimensional mesh interconnect with wormhole routing. These include algorithms that are asymptotically optimal for short vectors (O(log(p)) for p processing nodes) and for long vectors (O(n) for n data elements per node), as well as hybrid algorithms that are superior for intermediate n. Performance models are developed that include the effects of link conflicts and other characteristics of the underlying communication system. The models are validated using experimental data from the Intel Touchstone DELTA computer. Each of the combine algorithms is shown to be superior under some circumstances. DOE

COMPARISON OF A DISTRIBUTED KALMAN FILTER VERSUS A CENTRALIZED KALMAN FILTER WITH FAULT DETECTION CONSIDERATIONS M.S. Thesis
Paul J. Lawrence, Jr. 30 Jul. 1993 280 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A270713; AFIT/GE/Eng/93S-06) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This project examined the results obtained by simulating an aircraft navigation system with a partial complement of a typical avionics sensor array. Two different techniques of estimation processes were utilized and compared: the conventional Kalman and the federated filter architectures. Areas of interest include error state estimation accuracy and overall performance, residual behavior under normal and induced sensor failure conditions, and potential for failure detection and isolation. Several simulations were accomplished for each filter design and the results were compared in order to verify the validity of the newly developed federated filter architecture. Comparison of the error state estimation accuracies of the two filter designs revealed excellent overall performances for both. The identification of failures showed a definite advantage in the federated filter design. Having sensor-dedicated local filters allowed for easy sensor failure identification for the federated filter, while the centralized filter design suffered from navigation solution corruption under the same circumstances. Once established as a valuable estimation technique, the federated filter will add significantly to the viable alternatives when choosing a particular filter architecture for current avionics modifications or future avionics implementations. INTERVAL TIMED COLOURED PETRI NETS AND THEIR ANALYSIS
W. M. P. vanderAalst 1992 29 p See also PB92-200641 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191732; COMPUTING SCIENCE NOTES-92/17) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The paper presents the Interval Timed Colored Petri Net (ITCPN) model. An interval timed colored Petri net is a colored Petri net extended with time; time is in tokens, and transitions determine a delay for each produced token. The delay is specified by an upper and lower bound, i.e. an interval. The ITCPN model allows the modelling of the dynamic behavior of large and complex systems, without losing the possibility of formal analysis. In addition to the existing analysis techniques for colored Petri nets, the author proposes a new analysis method to analyze the temporal behavior of the net. This method constructs a reduced reachability graph and exploits the fact that delays are described by an interval. NTIS

TOTAL ORDER ASSUMPTION
J. C. M. Baeten 1992 19 p See also N91-25722 and N92-30178 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191740; COMPUTING SCIENCE NOTES-92/14) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The total order assumption (TOA) is the assumption that all execution sequences of observable actions or events are totally ordered by precedence. As long as in some cases TOA is to the point, total order and partial order semantics are both legitimate but lead to different theories. The author argues that TOA is a simplifying assumption and presents an example of a total order theory without interleaving and a partial order theory with interleaving. NTIS

PROGRAM DERIVATION IN ACYCLIC GRAPHS AND RELATED PROBLEMS
J. P. H. W. vandenEijnde 1992 92 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191765; COMPUTING SCIENCE NOTES-92/04) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Several derivations of algorithms on acyclic graphs are presented. Acyclic graphs are shown to be important for the solution of a general form of recursive equations and, as such, appear everywhere in the practice of programming. The central problem of the paper concerns the computation of a general class of functions on the vertex set of an acyclic graph, defined by a particular form of recursive equation, which is shown to have a unique solution. Solving this problem gives rise to two interesting subproblems: graph inversion; and topological sorting. For these problems, compact derivations of algorithms are presented as well. The central problem is also solved for equations additionally satisfying a certain split property, leading to a more elegant algorithm. Finally, the practical applicability of the theory is demonstrated by means of a number of typical examples satisfying this split property. NTIS

EFFICIENT AND CORRECT TRANSLATION OF STRICT APPLICATIVE PROGRAMMING LANGUAGES Ph.D. Thesis [EFFIZIENTE UND KORREKTE UEBERSETZUNG STRIKTER APPLIKATIVER PROGRAMMIERSPRACHEN]
Wolfram Schulte 1992 119 p In GERMAN
(ETN-93-95056) Avail: CASI HC A06/MF A02

The applicative programming language OPAL is translated into the imperative programming language C; it is investigated whether the dynamic running of strict functional programs on sequential von Neumann machines is necessarily more inefficient than the running of imperative programs. The translation was divided into three parts: the analysis of structure and context conditions of OPAL in the extended lambda calculation was completed with pattern matching and structures parametrization was followed by operations parametrization; in the transformation phase, the code was sequentialized and normalized after functions are unfolded and specialized on the application level; for code production, iterative and linear recursive recursion were depicted on loops. The software was evaluated in terms of robustness, correctness, simplicity, portability, adaptability, and efficiency. The implementation of the translation system for its proper construction shows it is usable for bigger programs too and the integration of software in language C is possible with reduced costs. ESA

ROBUST AND EFFICIENT 3D RECOGNITION BY ALIGNMENT

Tao D. Alter Sep. 1992 132 p

(Contracts N00014-85-K-0124; DACA76-85-C-0010)

(AD-A270839; AI-TR-1410) Avail: CASI HC A07/MF A02

Alignment is a prevalent approach for recognizing three-dimensional objects in two-dimensional images. Current implementations handle errors that are inherent in images in ad hoc ways. This thesis shows that these errors can propagate and magnify through the alignment computations, such that the ad hoc approaches may not work. In addition, a technique is given for tightly bounding the propagated error, which can be used to make the recognition robust while still being efficient. Further, the error bounds can be used to formally compute the likelihood that a set of hypothesized matches between model and image features is correct. The technique for bounding the propagated error makes use of a new solution to a fundamental problem in computer recognition, namely, the solution for 3D pose from three corresponding points under weak-perspective projection. The new solution is intended to provide a fast means of computing the error bounds. In deriving the new solution, this thesis gives a geometrical interpretation to the problem, from which the situations are inferred where the solution does not exist and is unstable. DTIC

A WEIGHTED LEAST-SQUARES LUMP CORRECTION ALGORITHM FOR TRANSMISSION-CORRECTED GAMMA RAY NONDESTRUCTIVE ASSAY

T. H. Prettyman, J. K. Sprinkle, Jr., and G. A. Sheppard 1993 10 p Presented at the 34th Annual Meeting of the Institute of Nuclear Materials Management, Scottsdale, AZ, 18-21 Jul. 1993

(Contract W-7405-eng-36)

(DE93-018474; LA-UR-93-2632; CONF-930749-60) Avail: CASI HC A02/MF A01

With transmission-corrected gamma-ray nondestructive assay instruments such as the Segmented Gamma Scanner (SGS) and the Tomographic Gamma Scanner (TGS) that is currently under development at Los Alamos National Laboratory, the amount of gamma-ray emitting material can be underestimated for samples in which the emitting material consists of particles or lumps of highly attenuating material. This problem is encountered in the assay of uranium and plutonium-bearing samples. To correct for this source of bias, the authors have developed a least-squares algorithm that uses transmission-corrected assay results for several emitted energies and a weighting function to account for statistical uncertainties in the assay results. The variation of effective lump size in the fitted model is parameterized; this allows the correction to be performed for a wide range of lump-size distributions. It may be possible to use the reduced chi-squared value obtained in the fit to identify samples in which assay assumptions have been violated. The authors find that the algorithm significantly reduces bias in simulated assays and improves SGS assay results for plutonium-bearing samples. Further testing will be conducted with the TGS, which is expected to be less susceptible than the SGS to systematic source of bias. DOE

CTH: A SOFTWARE FAMILY FOR MULTI-DIMENSIONAL SHOCK PHYSICS ANALYSIS

E. S. Hertel, Jr., R. L. Bell, M. G. Elrick, A. V. Farnsworth, G. I. Kerley, J. M. McGlaun, S. V. Petney, S. A. Silling, P. A. Taylor, and L. Yarrington 1992 6 p Presented at the 19th International Symposium on Shock Waves, Marseille, France, 26-30 Jul. 1993

(Contract DE-AC04-76DP-00789)

(DE93-019428; SAND-92-2089C; CONF-930788-3) Avail: CASI HC A02/MF A01

CTH is a family of codes developed at Sandia National Laboratories for modeling complex multi-dimensional, multi-material problems that are characterized by large deformations and/or strong shocks. A two-step, second-order accurate Eulerian solution algorithm is used to solve the mass, momentum, and energy conservation equations. CTH includes models for material strength, fracture, porous materials, and high explosive detonation and initiation. Viscoplastic or rate-dependent models of material strength have been added recently. The formulations of Johnson-Cook, Zerilli-Armstrong, and Steinberg-Guinan-Lund are standard options within CTH. These models rely on using an internal state variable to account for the history dependence of material response. The implementation of internal state variable models is discussed and several sample calculations are presented. Comparison with experimental data is made among the various material strength models. The advancements made in modelling material response have significantly improved the ability of CTH to model complex, large-deformation, plastic-flow dominated phenomena. Detonation of energetic material under shock loading conditions has been of great interest. A recently developed model of reactive burn for high explosives (HE) has been added to CTH. This model along with newly developed tabular equations-of-state for the HE reaction by-products has been compared to one- and two-dimensional explosive detonation experiments. These comparisons indicate excellent agreement of CTH predictions with experimental results. The new reactive burn model coupled with the advances in equation-of-state modeling make it possible to predict multi-dimensional burn phenomena without modifying the model parameters for different dimensionality. Examples of the features of CTH are given. The simulations shown are compared with well characterized experiments covering key phenomena of shock physics. DOE

A COMPUTATIONAL THEORY OF LEXICAL RELATEDNESS

Marc Light Feb. 1993 42 p

(Grant NSF IRI-90-13160)

(TR-421) Avail: CASI HC A03/MF A01

Lexicon coverage is often the limiting factor in natural language processing (NLP) systems. Recent work has attempted to remedy this situation by extracting information from machine readable dictionaries. Unfortunately, no NLP lexicon system or dictionary could possibly list all the potential words of English. However, humans are often able to interpret novel word forms (that is, words they have not seen before) without difficulty. One way we do this, if the word is complex (e.g. undecidability), is by using cues from the internal structure of the word. Relations in phonological form often correspond to relations in meaning. For example, if someone knows what the verb open means, a number of educated guesses can be made about the meaning of reopen. Exceptions abound in lexical data and any system that attempts to use lexical generalizations must be able to handle exceptions in a principled fashion. I describe the preliminary design of a system that uses relations in form to derive relations in meaning. For a new word, the system will produce meaning postulates that represent an educated guess about the meaning of the new word. These meaning postulates are written in Episodic Logic and the entire system will be a module of the TRAINS system. Author (revised)

A SOFTWARE ARCHITECTURE FOR THE CONSTRUCTION AND MANAGEMENT OF REAL-TIME VIRTUAL WORLDS Ph.D. Thesis

David R. Pratt Jun. 1993 158 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A271465) Avail: CASI HC A08

As military budgets shrink, the Department of Defense (DoD) is turning to virtual worlds (VW) to solve problems and address issues that were previously solved by prototype or field exercises. However, there is a critical void of experience in the community on how to build VW systems. The Naval Postgraduate School's Network Vehicle Simulator (NPSNEI) was designed and built to address this need. NPSNET is a populated, networked, interactive, flexible, three dimensional (3D) virtual world system. This dissertation covers the construction and management of the VW in NPSNET. The system, which uses both standard and non-standard network message formats, is fully networked allowing multiple users to interact simultaneously in the VW. Commercial off the shelf (COTS), Silicon Graphics Incorporated (SGI) workstations hardware was used exclusively in NPSNET to ensure the usefulness and the portability of the system to many DoD commands. The core software architecture presented here is suitable for any VW. DTIC

Software quality assurance is an area of concern for DOE, EPA, and other agencies due to the poor quality of software and its documentation they have received in the past. This report briefly summarizes the software development concepts and terminology increasingly employed by these agencies and provides a workable approach to scientific programming under the new requirements. Following this is a practical description of how to qualify a simulation code, based on a software QA plan that has been reviewed and officially accepted by DOE/OCRWM. Two codes have recently been baselined and qualified, so that they can be officially used for QA level 1 work under the DOE/OCRWM QA requirements. One of them was baselined and qualified within one week. The first of the codes was the multi-phase multi-component flow code, TOUGH version 1, an already existing code, and the other was a geochemistry transport code, STATEQ, that was under development. The way to accomplish qualification for both types of codes is summarized in an easy-to-follow step-by-step fashion to illustrate how to baseline and qualify such codes through a relatively painless procedure. A COMPREHENSIVE SOFTWARE ENGINEERING EDUCATIONAL EXPERIENCE
George C. Harrison 15 Aug. 1993 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA972-92-J-1024)
(AD-A270583) Avail: CASI HC A03

The original plan of the project outlined in the proposal in Aug. of 1991 was to experiment with possible solutions to the problems of offering a comprehensive software engineering course to undergraduates. The target student was assumed to be a junior computer science major with programming experience in Pascal through our CSC 260 (Computer Programming II) course. This course is analagous to the ACM designated CS2 course. Some of the problems with software engineering education to undergraduates were identified to be: (1) The inability to complete quality documents (user's manuals, requirements specifications, and detailed design) and implement the project during one 14 week semester; (2) Since the ARPA call for proposals included an Ada education component, I felt that it was impossible to have students without an Ada background to complete the implementation of the software engineering project; and (3) The lack of undergraduate experience in the use of CASE tools. MINT TUTORIAL AND USER MANUAL
Jack E. Veenstra May 1993 39 p
(Grant NSF CDA-88-22724)
(TR-452) Avail: CASI HC A03/MF A01

Mint, a MIPS code interpreter for parallel programs, is described. Mint generates memory reference traces that can be used to drive simulations of multiprocessor systems. Mint executes in a single address space and interprets MIPS R3000 object code programs. For faster interpretation, blocks of straight-line code in the object program are executed natively by creating functions at run-time. Unlike other memory tracers that compile the memory tracing calls into the simulated program, Mint does not require recompiling the simulated program. Interpreting the object program has the advantage that no source is needed, the simulator is independent of the object program, and a total program trace, including library references, is easily generated. Mint is a fast interpreter. When generating events for every memory reference, the overhead of Mint typically slows down a simulated program by a factor of 20 to 70 compared to its native execution time. Author (revised)

DATA MANAGEMENT FOR SUPPORT OF THE OREGON TRANSECT ECOSYSTEM RESEARCH (OTTER) PROJECT
J. W. Skiles and Gary L. Angelici (Sterling Software, Inc., Palo Alto, CA.) Nov. 1993 48 p
(Contract NAS2-13712)
(NASA-CR-4557; A-94020; NAS 1.26:4557) Avail: CASI HC A03/MF A01

Management of data collected during projects that involve large numbers of scientists is an often overlooked aspect of the experimental plan. Ecosystem science projects like the Oregon Transect Ecosystem Research (OTTER) Project that involve many investigators from many institutions and that run for multiple years, collect and archive large amounts of data. These data range in size from a few kilobytes of information for such measurements as canopy chemistry and meteorological variables, to hundreds of megabytes of information for such items as views from multi-band spectrometers flown on aircraft and scenes from imaging radiometers aboard satellites. Organizing and storing data from the OTTER Project, certifying those data, correcting errors in data sets, validating the data, and distributing those data to other OTTER investigators is a major undertaking. Using the National Aeronautics and Space Administration's (NASA) Pilot Land Data System (PLDS), a Support mechanism was established for the OTTER Project which accomplished all of the above. At the onset of the interaction between PLDS and OTTER, it was not certain that PLDS could accomplish these tasks in a manner that would aid researchers in the OTTER Project. This paper documents the data types that were collected under the auspices of the OTTER Project and the procedures implemented to store, catalog, validate, and certify those data. The issues of the compliance of investigators with data-management requirements, data use and certification, and the ease of retrieving data are discussed. We advance the hypothesis that formal data management is necessary in ecological investigations involving multiple investigators using many data gathering instruments and experimental procedures. The issues and experience gained in this exercise give an indication of the needs for data management systems that must be addressed in the coming decades when other large data-gathering endeavors are undertaken by the ecological science community. PREVAIL-DM: A FRAMEWORK-BASED ENVIRONMENT FOR FORMAL HARDWARE VERIFICATION
Flavio Rech Wagner Jul. 1992 32 p
(RR-899; ETN-93-94989) Avail: CASI HC A03/MF A01

The framework based PREVAIL-DM design environment for formal hardware verification is described. PREVAIL-DM integrates proof tools that are available in the PREVAIL environment around a common, Very Hardware Description Language (VHDL) based conceptual schema. Tools are encapsulated according to a black box approach. Design data are stored in a unique data base, and the environment offers a common main user interface, which gives access to design tools and methods and allows browsing through the database objects. Available methods to be applied on the design objects are oriented to the application semantics, thus helping to maintain all desired schema related integrity constraints. PREVAIL-DM is implemented upon the Cadlab framework and uses most of its main features. ESA

FAST SCALAR ALGORITHMS FOR MULTIVARIATE PARTIAL CORRELATIONS AND THEIR EMPIRICAL COUNTERPARTS
Dinh Tuan Pham Oct. 1992 27 p
(RR-903-M; ETN-93-94994) Avail: CASI HC A03/MF A01

Algorithms for computing the triangular partial correlation matrices and the scalar partial autocorrelation coefficients and their empirical counterparts, as well as for the conversion between the two types of partial correlations, are derived. Although these algorithms deal with multivariate time series, they work with scalars and vectors, avoiding any matrix operation, and hence are quite efficient computationally. ESA

DISTRIBUTED VIRTUAL SYSTEM (DIVIRS) PROJECT Semiannual Progress Report No. 11
Herbert Schorr and B. Clifford Neuman Nov. 1993 23 p
(Contract NCC2-539)
(NASA-CR-194360; NAS 1.26:194360) Avail: CASI HC A03/MF A01

As outlined in the continuation proposal 92-ISI-50R (revised) on NASA cooperative agreement NCC 2-539, the investigators are developing software, including a system manager and a job manager, that will manage available resources and that will enable programmers to develop and execute parallel applications in terms of a virtual configuration of processors, hiding the mapping to physical nodes; developing communications routines that support

the abstractions implemented; continuing the development of file and information systems based on the Virtual System Model; and incorporating appropriate security measures to allow the mechanisms developed to be used on an open network. The goal throughout the work is to provide a uniform model that can be applied to both parallel and distributed systems. The authors believe that multiprocessor systems should exist in the context of distributed systems, allowing them to be more easily shared by those that need them. The work provides the mechanisms through which nodes on multiprocessors are allocated to jobs running within the distributed system and the mechanisms through which files needed by those jobs can be located and accessed. APPLYING THE INN MODEL TO THE MaxClique
T. Grossman 1993 13 p Presented at the 2nd Dimacs Challenge Conference, New Brunswick, NJ, 11-13 Oct. 1993
(Contract W-7405-eng-36)
(DE93-040137; LA-UR-93-3082; CONF-9310154-1) Avail: CASI HC A03/MF A01

Max-Clique is the problem of finding the largest clique in a given graph. It is not only NP-hard, but, as recent results suggest, even hard to approximate. Nevertheless, it is still very important to develop and test practical algorithms that will find approximate solutions for the maximum clique problem on various graphs stemming from numerous applications. Indeed, many different types of algorithmic approaches are applied to that problem. Several neural networks and related algorithms were applied recently to combinatorial optimization problems in general and to the Max-Clique problem in particular. These neural nets are dynamical system which minimize a cost (or computational 'energy') function that represents the optimization problem, the Max-Clique in our case. Therefore, they all belong to the class of integer programming algorithms surveyed in the Pardalos and Xue review. The work presented here is a development and improvement of a neural network algorithm that was introduced recently. In the previous work, we have considered two Hopfield type neural networks, the INN and the HcN, and their application to the Max-Clique problem. In this paper, I concentrate on the INN network and present an improved version of the t-A algorithm that was introduced in. The rest of this paper is organized as follows. In section 2, I describe the INN model and how it implements a given graph. In section 3, it is characterized in terms of graph theory. In particular, the stable states of the network are mapped to the maximal cliques of its underling graph. In section 4, I present the t-Annealing algorithm and an improved version of it, the Adaptive t-Annealing. Several experiments done with these algorithms on benchmark graphs are reported in section 5, and the efficiency of the new algorithm is demonstrated. I conclude with a short discussion. DOE

OBJECT-ORIENTED DFD MODELS TO PRESENT THE FUNCTIONAL AND BEHAVIORAL VIEWS
A. Maxted Jun. 1993 18 p
(Contract DE-AC04-76DP-00789)
(DE93-040206; SAND-93-0940) Avail: CASI HC A03/MF A01

An object-oriented methodology is presented that is based on two sets of Data Flow Diagrams (DFD's): one for the functional view, and one for the behavioral view. The functional view presents the information flow between shared objects. These objects map to the classes identified in the structural view (e.g., Information Model). The behavioral view presents the flow of information between control components and relates these components to their state models. Components appearing in multiple views provide a bridge between the views. The top-down hierarchical nature of the DFDs provide a needed overview or road map through the software system. DOE

A PROPOSAL FOR REVERSE ENGINEERING CASE TOOLS TO SUPPORT NEW SOFTWARE DEVELOPMENT
A. Maxted Jun. 1993 12 p
(Contract DE-AC04-76DP-00789)
(DE93-040207; SAND-93-0941) Avail: CASI HC A03/MF A01

Current CASE technology provides sophisticated diagramming tools to generate a software design. The design, stored internal to the CASE tool, is bridged to the code via code generators. There are several limitations to this technique: (1) the portability of the design is limited to the portability of the CASE tools, and (2) the code generators offer a clumsy link between design and code. The CASE tool, though valuable during design, becomes a hindrance during implementation. Frustration frequently causes the CASE tool to be abandoned during implementation, permanently severing the link between design and code. Current CASE stores the design in a CASE internal structure, from which code is generated. The technique presented herein suggests that CASE tools store the system knowledge directly in code. The CASE support then switches from an emphasis on code generators to employing state-of-the-art reverse engineering techniques for document generation. Graphical and textual descriptions of each software component (e.g., Ada Package) may be generated via reverse engineering techniques from the code. These reverse engineered descriptions can be merged with system over-view diagrams to form a top-level design document. The resulting document can readily reflect changes to the software components by automatically generating new component descriptions for the changed components. The proposed auto documentation technique facilitates the document upgrade task at later stages of development, (e.g., design, implementation and delivery) by using the component code as the source of the component descriptions. The CASE technique presented herein is a unique application of reverse engineering techniques to new software systems. This technique contrasts with more traditional CASE auto code generation techniques. DOE

FEATURE-BASED TOLERANCING FOR INTELLIGENT INSPECTION PROCESS DEFINITION
C. W. Brown Jul. 1993 13 p Presented at the Forum on Dimensional Tolerancing and Metrology, Dearborn, MI, 17-19 Jun. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00613)
(DE93-017984; KCP-613-5260; CONF-9306209-1) Avail: Issuing Activity (Department of Energy (DOE))

This paper describes a feature-based tolerancing capability that complements a geometric solid model with an explicit representation of conventional and geometric tolerances. This capability is focused on supporting an intelligent inspection process definition system. The feature-based tolerance model's benefits include advancing complete product definition initiatives (e.g., STEP - standard for exchange of product model data), supplying computer-integrated manufacturing applications (e.g., generative process planning and automated part programming) with product definition information, and assisting in the solution of measurement performance issues. A feature-based tolerance information model is developed based upon the notion of a feature's tolerance aspects and describes an object-oriented scheme for representing and relating tolerance features, tolerances, and datum reference frames. For easy incorporation, the tolerance feature entities are interconnected with STEP solid model entities. This schema will explicitly represent the tolerance specification for mechanical products, support advanced dimensional measurement applications, and assist in tolerance-related methods divergence issues. THREE-DIMENSIONAL DYNAMIC THERMAL IMAGING OF STRUCTURAL FLAWS BY DUAL-BAND INFRARED COMPUTED TOMOGRAPHY
N. K. DelGrande, K. W. Dolan, P. F. Durbin, M. R. Gorvad, B. T. Kornblum, D. E. Perkins, D. J. Schneberk, and A. B. Shapiro Apr. 1993 12 p Presented at the Society of Photo-Optical Instrumentation Engineers (SPIE) OE/Aerospace Science and Sensing Meeting, Orlando, FL, 11-16 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-019575; UCRL-JC-113744; CONF-930445-23) Avail: CASI HC A03

This paper discusses three-dimensional (3D) dynamic thermal imaging of structural flaws using dual-band infrared (DBIR) computed tomography. Conventional thermography provides single-band infrared images which are difficult to interpret. Standard procedures yield imprecise (or qualitative) information about sub-surface flaw sites which are typically masked by surface clutter. The authors use a DBIR imaging technique pioneered at

LLNL to capture the time history of surface temperature difference for flash-heated targets. They relate these patterns to the location, size, shape, and depth of subsurface flaws. The authors demonstrate temperature accuracies of 0.2 C, timing synchronizations of 3 ms (after onset of heat flash), and intervals of 42 ms, between images, during an 8 s cooling (and heating) interval characterizing the front (and back) surface temperature-time history of an epoxy-glue disbond site in a flash-heated aluminum lap joint. This type of disbond played a significant role in causing damage to the Aloha Aircraft fuselage on the aged Boeing 737 jetliner. By ratioing DBIR images (near 5 and 10 micron), the authors located surface temperature patterns (generated by weak heat flow anomalies at subsurface flaw sites) and removed the emissivity mask (from surface roughness variations). They compared measurements with calculations from the three-dimensional, finite element computer code TOPAZ3D. They combined infrared, ultrasound, and x-ray imaging methods to characterize the lap joint disbond site spatial, bond quality, and material differences. DOE

Presently, the problem of over-all library system design has been compounded by the accretion of both function and structure to a basic framework of requirements. While more device power has led to increased functionality, opportunities for reducing system complexity at the user interface level have not always been pursued with equal zeal. The purpose of this book is therefore to set forth and examine these opportunities, within the general framework of human factors research in man-machine interfaces. Human factors may be viewed as a series of trade-off decisions among four polarized objectives: machine resources and user specifications; functionality and user requirements. In the past, a limiting factor was the availability of systems. However, in the last two years, over one hundred libraries supported by many different software configurations have been added to the Internet. This document includes a statistical analysis of human responses to five Internet library systems by key features, development of the ideal online catalog system, and ideal online catalog systems for libraries and information centers. This invention relates to a reconfigurable fuzzy cell comprising a digital control programmable gain operation amplifier, an analog-to-digital converter, an electrically erasable PROM, and 8-bit counter and comparator, and supporting logic configured to achieve in real-time fuzzy systems high throughput, grade-of-membership or membership-value conversion of multi-input sensor data. The invention provides a flexible multiplexing-capable configuration, implemented entirely in hardware, for effectuating S-, Z-, and PI-membership functions or combinations thereof, based upon fuzzy logic level-set theory. A membership value table storing 'knowledge data' for each of S-, Z-, and PI-functions is contained within a nonvolatile memory for storing bits of membership and parametric information in a plurality of address spaces. Based upon parametric and control signals, analog sensor data is digitized and converted into grade-of-membership data. In situ learn and recognition modes of operation are also provided.

CLOSURE PROPERTIES OF STOCHASTIC LANGUAGES
Ioan Macarie Jan. 1993 27 p
(Grant NSF IRI-90-03841)
(TR-441) Avail: CASI HC A03/MF A01

The study of probabilistic one-way finite-state automata has been sparsely spread over at least thirty-three years, and across media that are not all readily accessible in the West at the present time. In a uniform setting, we present properties of the classes of languages specifiable by such automata. We present results found in a wide and nonhomogeneous literature together with original results. Along with probabilistic automata, we also study a clean generalized version. The classes of languages accepted by such automata are defined in terms of numerical cutpoints and the functions that these automata compute. Our main results are some closure properties for the classes and functions. We give a technique for proving stochasticity and we apply it in the case of some well known languages. Author

EXPLANATION CLOSURE, ACTION CLOSURE, AND THE SANDEWALL TEST SUITE FOR REASONING ABOUT CHANGE
Lenhart K. Schubert Oct. 1992 22 p
(Contracts N00014-82-K-0193; F30602-91-C-0010)
(TR-440) Avail: CASI HC A03/MF A01

Explanation closure (EC) axioms were previously introduced as a means of solving the frame problem. This paper provides a thorough demonstration of the power of EC (combined with action closure) for reasoning about dynamic worlds, by way of Sandewall's recently compiled test suite of 12-or-so problems. The problems range from the 'Yale turkey shoot' (and variants) to the 'stuffy room' problem, and were intended as a test and challenge for nonmonotonic logics of action. The EC/AC-based solutions for the most part do not resort to nonmonotonic reasoning at all, yet fare much better in providing the intuitively warranted inferences than the best known nonmonotonic approaches. While there are good reasons for ultimately employing nonmonotonic or probabilistic logics--e.g., pervasive uncertainty and the qualification problem--this does show that the scope of monotonic methods has been underestimated. Subsidiary purposes of the paper are to clarify the intuitive status of EC axioms in relation to action effect axioms; and to show how EC, previously formulated within the situation calculus, can be applied within the framework of a temporal logic similar to Sandewall's 'discrete fluent logic,' with some gains in clarity. A COMPARISON OF SOME OF THE MOST CURRENT METHODS OF IMAGE COMPRESSION M.S. Thesis
Robert T. Kay Jun. 1993 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271841) Avail: CASI HC A05

In this report, commonly used lossless and lossy image compression algorithms are heuristically presented and then compared in terms of performance. The lossy algorithms, JPEG (Joint Photographic Experts Group) and Fractal compression, are compared in terms of their respective sensitivities between compression ratio and image fidelity. Compression algorithms based on the lossless models of Huffman, Adaptive Huffman, and arithmetic coding are compared in terms of compression ratio and compression/decompression time requirements. High fidelity image reconstructions of JPEG and fractal compressions are also included in the comparison. Results, for the images tested, indicate that if imperceptible losses in fidelity can be tolerated, then among the current versions of the algorithms tested, the JPEG results in higher compression with less process time. THRESHOLD COMPUTATION AND CRYPTOGRAPHIC SECURITY
Yenjo Han, Lane A. Hemachandra, and Thomas Thierauf (Ulm Univ., Germany.) 12 Nov. 1992 29 p
(Grants NSF CCR-89-57604; NSF CCR-90-57486)
(TR-443) Avail: CASI HC A03/MF A01

Threshold machines are Turing machines whose acceptance is determined by what portion of the machine's computation paths are accepting paths. Probabilistic machines are Turing machines whose acceptance is determined by the probability weight of the machine's accepting computation paths. Simon proved that for unbounded-error polynomial-time machines these two notions yield the same class, PP. Perhaps because Simon's result seemed to collapse the threshold and probabilistic modes of computation, the relationship between threshold and probabilistic computing

for the case of bounded error has remained unexplored. In this paper, we compare the bounded-error probabilistic class BPP with the analogous threshold class, BPP(sub path), and, more generally, we study the structural properties of BPP(sub path). We prove that BPP(sub path) contains both NP(sup BPP) and P(sup NP(log)), and that BPP(sub path) is contained in P(sup summation 2 to p of (log)), BPP(sup NP), and PP. We conclude that, unless the polynomial hierarchy collapses, bounded-error threshold computation is strictly more powerful than bounded-error probabilistic computation. We also formalize the natural notion of secure access to a database: an adversary who watches the queries should gain no information about the input other than perhaps its length. We show, for both BPP and BPP(sub path), that if there is any database for which this formalization of security differs from the security given by oblivious database access, then P not equal to PSPACE. It follows that if any set lacking small circuits can be securely accepted, then P not equal to PSPACE. Author

STANDARD ML SIGNATURES FOR A PROTOCOL STACK

Edoardo Biagioni, Robert Harper, and Peter Lee Oct. 1993 18 p

(Contract F19628-91-C-0168; ARPA Order 8313)

(AD-A272060; CMU-CS-93-170) Avail: CASI HC A03/MF A01

This paper describes the design of a protocol stack implemented in Standard ML. Standard ML's signatures are a language construct which can be used to specify or constrain the interface of a module. The design includes both a generic signature which generalizes all the protocol modules, and individual signatures specific to each protocol module. The specific signatures all inherit from the generic signature. The implementation of each protocol is parametrized, so protocols can be composed into custom protocol stacks. The parameter to each protocol is constrained only by the generic signature, and this lets any protocol instance satisfying a specific signature be used as the parameter to any other protocol. As a result, the design and implementation are highly modular, and syntactic compatibility between modules is checked by the compiler. To provide some context for the discussion of the signatures, some of the details of the implementation are also presented. DTIC

TEST AND EVALUATION: DOD HAS BEEN SLOW IN IMPROVING TESTING OF SOFTWARE-INTENSIVE SYSTEMS

Sep. 1993 57 p

(AD-A271541; GAO/NSIAD-93-198) Avail: CASI HC A04/MF A01

Department of Defense (DoD) software cost total over $30 billion a year (estimated to be $42 billion by 1995), of which about two-thirds is for maintaining upgrading and modifying operational systems already in production. Today's major defense systems depend largely on the quality of this complex and increasingly costly software. In fact, many major weapon systems cannot operate if the software fails to function as required. Because software errors can cause a system to fail, possibly with life-threatening consequences, software-intensive systems need to be thoroughly tested before production. Since the early 1970's, GAO has reported problems in operational test and evaluation of defense acquisition programs. Senior DoD officials, as well as members of the Congress, are concerned that many of these problems continue today, particularly in software-intensive systems. Because of these concerns, GAO initiated this review to identify (1) the extent that software-related problems affect the performance of defense acquisition programs during operational test and evaluation, (2) pervasive barriers in the acquisition process that limit the effectiveness of the test and evaluation of software-intensive systems, and (3) DoD's effort to resolve software test and evaluation problems. Although GAO recognizes that inherently complex technical characteristics contribute to software problems, this report focuses more directly on nontechnical barriers that limit the effectiveness of operational test and evaluation and need management attention. CAUSAL RECONSTRUCTION

Gary C. Brochardt Feb. 1993 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-91-J-4038)

(AD-A271692; AIM-1403) Avail: CASI HC A04

Causal reconstruction is the task of reading a written causal description of a physical behavior, forming an internal model of the described activity, and demonstrating comprehension through question answering. This task is difficult because written descriptions often do not specify exactly how referenced events fit together. This article characterizes the causal reconstruction problem; presents a representation called transition space, which portrays events in terms of transitions, or collections of changes expressible in everyday language; and describes a program called PATHFINDER, which uses the transition space representation to perform casual reconstruction on simplified English descriptions of physical activity. PATHFINDER works by identifying partial matches between the representations of events and using these matches to form causal chains, fill causal gaps, and merge overlapping accounts of activity. By applying transformations to events prior to matching, PATHFINDER is also able to handle a range of discontinuities arising from a writer's use of analogy or abstraction. DTIC

MEASURING THE EFFECTS OF THREAD PLACEMENT ON THE KENDALL SQUARE KSR1

T. D. Wagner, E. Smirni, A. W. Apon, M. Madhukar, and L. W. Dowdy Aug. 1993 29 p

(Contract DE-AC05-84OR-21400)

(DE93-040655; ORNL/TM-12462) Avail: CASI HC A03/MF A01

This paper describes a measurement study of the effects of thread placement on memory access times on the Kendall Square multiprocessor, the KSR1. The KSR1 uses a conventional shared memory programming model in a distributed memory architecture. The architecture is based on a ring of rings of 64-bit superscalar microprocessors. The KSR1 has a Cache-Only Memory Architecture (COMA). Memory consists of the local cache memories attached to each processor. Whenever an address is accessed, the data item is automatically copied to the local cache memory module, so that access times for subsequent references will be minimal. Experiments run on the KSR1 across a wide variety of thread configurations show that shared memory access is accelerated through strategic placement of threads which share data. The results indicate strategies for improving the performance of applications programs and illustrate that KSR1 memory access times can remain nearly constant even when the number of participating threads increases. AIDA: A GRAPHICAL INTERACTIVE SYSTEM, ADAPTED TO THE USER Ph.D. Thesis [AIDA: EIN AN DEN BENUTZER ANGEPASSTES GRAPHISCH-INTERAKTIVES SYSTEM]

Jairo Antonio CoteMunoz 1990 272 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ETN-93-93792) Avail: CASI HC A12

The possibilities of improving man machine communication in a graphical interactive system are depicted with focus on the user support. The advantages of methods and technologies of artificial intelligence in such systems are examined. A tool for generation of user interfaces is presented: SIEMCAD is a user interface management system for integrating electronic and mechanical computer aided design. Models for better user support are presented: it was established, that user knowledge is an important influence factor on the mental user model. The AIDA model was developed with the theory of cognitive complexity, which takes into account user knowledge about technical graphics, computer graphics, and computer aided design systems. The AIDA model was examined from the point of view of tasks, semantics, and syntax. Strategies for the behavior of an adaptive system are presented. Architecture and implementation of AIDA are depicted. ESA

OPTIMAL SORTING IN LINEAR ARRAYS WITH MINIMUM GLOBAL CONTROL

Ferri Abolhassan (Saarland Univ., Saarbrucken, Germany.), Joerg Keller, and Dieter Scheerer (Saarland Univ., Saarbrucken, Germany.) Nov. 1992

9 p Sponsored in part by DFG Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract NF-62-376)
(CWI-CS-R9244; ETN-94-94724) Copyright Avail: CASI HC A02

Linear sorting arrays with a single global control wire are investigated. The lower bound on the necessary time to sort n numbers in such an array is shown to be 2n, in contrast to 3n in arrays without global control. A two phase sorting algorithm for arrays with a global control wire that matches the time bound of 2n is presented. As 2n is a lower bound for sorting arrays with sequential input and output, this implies that further global control cannot lead to any improvements as long as sequential input/output is assumed. The algorithm needs an array of minimum length (n/2). The scheme can be easily extended to eliminate duplicate numbers. One possible application of the algorithm is in packet routing for algorithms that need presorted inputs. ESA

PROVING RUN-TIME PROPERTIES OF GENERAL PROGRAMS W.R.T. CONSTRUCTIVE NEGATION
Elena Marchiori Nov. 1992 31 p Sponsored in part by EEC
(CWI-CS-R9245; ETN-94-94725) Copyright Avail: CASI HC A03/MF A01

Run time properties of general programs with relation to constructive negation, that is, termination and properties of the form of the arguments of the literals selected during the execution, are studied. SLD-CNF resolution, resolution with constructive negation and arbitrary selection rule, and LD-CNF resolution, resolution with constructive negation and PROLOG selection rule, are considered. The class of programs which terminate for all ground goals for arbitrary (respectively, PROLOG) selection rule is shown to coincide with the so called acyclic (respectively, acceptable) programs, and SLD-CNF (respectively, LD-CNF) resolution is shown to be sound and complete with relation to Clark's semantics for bounded goals and acyclic (respectively, acceptable) programs. These results are applied to the study of run time properties of general programs: two proof methods are introduced and their soundness is proven with relation to SLD-CNF and LD-CNF resolution. ESA

A DECLARATIVE APPROACH FOR FIRST-ORDER BUILT-IN'S OF PROLOG
Krysztof R. Apt (Amsterdam Univ., Netherlands.), Elena Marchiori, and Catuscia Palamidessi (Genoa Univ., Italy.) Nov. 1992 48 p Sponsored in part by EEC
(Grant CNR-89.00036.69)
(CWI-CS-R9246; ETN-94-94726) Copyright Avail: CASI HC A03/MF A01

A framework for studying PROLOG programs with various 'built-ins' that include arithmetic operations, and such metalogical relations like 'var' and 'ground' is presented. To this end, a declarative semantics is proposed and completeness of the PROLOG computation mechanism with relation to this semantics is proved. This semantics is shown to be fully abstract in an appropriate sense. A method for proving termination of PROLOG programs with 'built-ins' which uses these semantics is provided. The method is shown to be modular and is illustrated by proving termination of a number of programs including the unify program of Sterling and Shapiro. ESA

EFFICIENT COMPARISON BASED STRING MATCHING
Dany Breslauer and Zvi Galil (Columbia Univ., New York, NY.) Dec. 1992 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grants NSF CCR-90-14605; CDA-90-24735)
(CWI-CS-R9249; ETN-94-94729) Copyright Avail: CASI HC A03

The exact number of symbol comparisons that are required to solve the string matching problem is studied and a family of efficient algorithms is presented. Unlike previous string matching algorithms, the algorithms in this family do not 'forget' results of comparisons, which makes their analysis much simpler. In particular, a linear time algorithm that finds all occurrences of a pattern of length m in a text of length n in $n + (((4 \log m + 2)/m)(n - m))$ comparisons is given. The pattern preprocessing takes linear time and makes at most 2m comparisons. This algorithm establishes that, in general, searching for a long pattern is easier than searching for a short one. It is shown that any algorithm in the family of the algorithms presented must make at least $n + ((\log m)((n - m)/m))$ symbol comparisons, for m 2 to the kth power - 1 and any integer k greater than or equal to 1. REPLICA CONTROL ALGORITHMS IN DISTRIBUTED DATABASES Final Report, 17 Jan. 1990 - 16 Jan. 1993
Sushil Jajodia Jul. 1993 3 p
(Grant AF-AFOSR-0135-90)
(AD-A271571; AFOSR-93-0787TR) Avail: CASI HC A01/MF A01

The effects of commutative transactions on distributed database performance was analyzed. The benefits were found to be insignificant unless the number of transactions was large. Two distributed algorithms for adaptive replication of data were developed, one which optimizes the communication cost objective function, and a second which optimizes communication time. A dynamic replication control algorithm was studied and showed improved performance over dynamic noting schemes. Concepts for using replicated data in multilevel secure databases showned the ability to guarantee one-copy serial ability using a small amount of trusted code. There were 14 articles published under this grant. DTIC

MULTIGRID APPROACH TO SOLVING THE LONG TRANSPORTATION PROBLEM ON A REGULAR GRID IN COST SPACE M.S. Thesis
Annette P. Cornett Jun. 1993 101 p
(AD-A272323) Avail: CASI HC A06/MF A02

Multigrid methods were developed to solve partial differential equations. Research has shown that these methods are applicable to a broader range of problems. This thesis investigates the application of multigrid techniques to minimal cost flow problems, specifically the long transportation problem. This research shows that multigrid techniques can be successfully applied to large-scale long transportation problems posed on a three-dimensional, regular grid in cost space. A V-cycle algorithm is developed for the long transportation problem. Analogies to the multigrid components of restriction, interpolation, and relaxation are detailed. Performance of the algorithm is discussed, and computational cost is analyzed. Future research is likely to include the development of more sophisticated restriction and interpolation schemes to provide integer-valued flows, and the development of a method to map an irregularly spaced problem to a regular grid, and to map the regular grid solution back to the original problem domain. GWB: MANUAL FOR THE GRAMMAR WORKBENCH VERSION 1.5
C. Dekkers, C. H. A. Koster, M.-J. Nederhof, and A. vanZwol Jul. 1992 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(TR-92-14; ETN-93-93868) Avail: CASI HC A03

The manual of the Grammar Work Bench (GWB), an environment for the comfortable development of Affix Grammars in the AGFL formalism, is presented. Its purposes are to: allow the user to input, inspect and modify a grammar; perform consistency checks on a grammar; compute grammar

properties; generate example sentences; assist in performing grammar transformations. The GWB is not a computer game. Its user interface is not supposed to be self explanatory, but the user is supposed to have read this manual. In particular, the user is supposed to know the commands. The GWB was developed for use in the Natural Language Front End (NLFE) project, aimed at the construction of comprehensive and well validated grammars and efficient parsers for a number of European languages. A SIMPLIFIED TOKEN BUS PROTOCOL SPECIFIED USING LOTOS
Luc Rooijakkers and Mieke Massink Jan. 1991 124 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(TR-92-15; ETN-93-93869) Avail: CASI HC A06

The use of the formal description technique LOTOS (Language Of Temporal Ordering Specification) is explored to specify a token bus protocol which serves as a non-trivial specification problem. The development of four specifications in different styles is described. The specifications were simulated with the SEDOS 'hippo' simulator. Only two out of four specifications (the resource constraint oriented and the resource state oriented) could be proved (strong) bisimulation equivalent although all specifications are correct with respect to the informal specification. To be able to analyze the equivalence of the constraint oriented and the resource constraint oriented specifications, these specifications were annotated with state information and transformed into a specification in a state oriented style. In that form they could more easily be compared with each other and with the original state oriented specifications. This analysis revealed that the resource constraint oriented and the constraint oriented specification have a different deadlock behavior and were only trace equivalent. The same holds for the constraint oriented against the state oriented specification. The state oriented and resource state oriented specifications could not be proved (bisimulation) equivalent due to buffering problems. An evaluation of the use of LOTOS, the different specification styles and the use of the SEDOS 'hippo' simulator are given. ESA

COCOLOG: A CONDITIONAL OBSERVER AND CONTROLLER LOGIC FOR FINITE MACHINES
Peter E. Caines (McGill Univ., Montreal, Quebec.) and Suning Wang (Spar Aerospace Ltd., Sainte-Anne-de-Bellevue, Quebec.) Jun. 1992 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant NSERC-A1329)
(INRIA-RR-1714; ETN-93-93913) Avail: CASI HC A03

The problem of observation and control for partially observed input-state-output machines is formulated in terms of a tree of first order logical theories. A set of first order languages for the description of the controlled evolution and state estimation of any given machine M is specified; further, conditional control axioms are formulated so that closed loop control actions occur when specified past observation dependent conditions are fulfilled. In particular, conditional control axioms may include commands that steer the system state from a current partially observed state (estimate) to a target state, if such a sequence of controls can be proved to exist. Starting from a general theory of M at the initial constant, observations on the input-output behavior of the system at any later instant are accepted by the system as new axioms; these are then used together with the previously generated theory to generate the current theory. The acronym COCOLOG is used to denote the family of first order Conditional Observer and Controller Logics for any given input-state-output system. A semantics is supplied for each COCOLOG in terms of interpretations of controlled transitions in a tree indexed by the possible sequences in input output observations. Extra-logical rules relating members of the family of theories of a COCOLOG are presented in the form of metalevel axioms and inference rules. Consistency and completeness of the first order theories in a COCOLOG family are established, decidability is obtained using a unique model property and examples of the operation of a COCOLOG logic control system are given. APPROXIMATE METHODS FOR N-COMPONENT SOLUTE TRANSPORT AND ION-EXCHANGE
P. M. C. Thoolen (Amsterdam Univ., Netherlands.) and P. W. Hemker (Amsterdam Univ., Netherlands.) Nov. 1992 20 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-NM-R9223; ETN-94-94698) Copyright Avail: CASI HC A03

The computation of ion exchange when an ambient groundwater of one uniform composition is displaced by an injection solution of a constant but differing composition is considered. The problem is to sort out the composition change from the initial to the injected compositions. An analytical method for the n dimensional homovalent system was described by Rhee, Aris, and Amundson. Conditions are given under which this method can be used to calculate an approximate solution to the plateau concentrations in the n dimensional heterovalent system. Two algorithms for the three component heterovalent system are derived from Chaberneau. A discretization method is introduced in which the concept of adaptive mesh refinement is applied. Such a method can be used in more complex situations and it still can represent sharp moving fronts. The results for the different approximate computations are compared for a real life problem. ESA

THE READINESS GROWTH MODEL: A QUANTITATIVE ANALYSIS OF SOFTWARE RISK Final Report, 1990 - 1993
David R. Castellano, Paul E. Janusz, and Sharyn L. Tolochko Oct. 1993 26 p
(AD-A272383; ARPAD-TR-93003) Avail: CASI HC A03/MF A01

The readiness growth model (RGM) developed in 1990 is a methodology used to quantitatively assess software maturity and, in turn, software readiness for test. It is comprised of data from many low level metrics, and provides a 'bottom line' assessment which managers can use to track software progress throughout the lifecycle. RGM can be used to assess the quality of both the process and the product, can identify problematic areas, and can determine associated risk. All of this information is summarized quickly by means of its graphical output and metric data. RGM has been successfully implemented on various U.S. Army Armament Research, Development and Engineering Center systems, supporting executive software/system readiness and fielding decisions. It has received high level endorsement from the program managers, and the Army and Office of the Secretary of Defense leadership that have applied it to date. DTIC

DESIGN OF A COMPUTER ASSISTED TOOL FOR OBJECT ORIENTED ACQUISITION, MODELING AND SIMULATION OF KNOWLEDGE STRUCTURE Ph.D. Thesis [KONZEPTION EINES RECHNERGESTUETZTEN WERKZEUGES ZUR OBJEKTORIENTIERTEN ERFASSUNG, MODELLIERUNG UND SIMULATION VON WISSENSSTRUKTUREN]
Joerg Papke 1992 182 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-94183) Avail: CASI HC A09

The computer assisted tool STRUKTOR for object oriented acquisition, modeling, and simulation of knowledge structures is presented. STRUKTOR belongs to a new generation of object oriented knowledge acquisition tools which profit from the advantages and the power of object oriented technology and open a future oriented dimension for knowledge engineering. The tool is a synthesis of the areas of graphic oriented knowledge engineering and object oriented programming. The dimensions of knowledge engineering were examined by the analysis of the individual knowledge acquisition methods, which can be categorized to the conventional systems analysis area as well as to the knowledge-based area. The ideas, concepts, and organization models of object oriented programming are discussed and the relations between knowledge engineering and object-oriented technology are highlighted. The system is presented with emphasis on the description of the features of this tool, the representation of the complex architecture, the components, and the organizationl model, which organizes the use of the components. THE ROBINSON-SCHENSTED AND SCHUETZENBERGER ALGORITHMS. PART 2: GEOMETRIC INTERPRETATIONS
Marc A. A. vanLeeuwen Dec. 1992 23 p Sponsored in part by Schweizerische Nationalfonds, Switzerland
(CWI-AM-R9209-Pt-2; ETN-94-94709) Copyright Avail: CASI HC A03/MF A01

There is a correspondence of Young tableaux to irreducible components of the variety F(sub u) of flags fixed by some unipotent element u a member of GL(sub n) and a correspondence of permutations to relative positions pairs of flags. Using these, Steinberg has given an interpretation of the Robinson-Schensted algorithm; this interpretation is developed and a similar interpretation for the Schuetzenberger algorithm is derived. These interpretations clarify many of the key properties of those algorithms which were treated purely combinatorially in part 1 of the study. Interpretations of the individual insertion and extraction procedures used in the Robinson-Schensted algorithm, and of their transposed variants, are given. The use of these algorithms to obtain explicit information (even if incomplete in general) about the irreducible components of the intersections of unipotent conjugacy classes in GL(sub n) with a Borel subgroup, the so called orbital varieties, is described. CLASSIFICATION IN FEATURE-BASED DEFAULT INHERITANCE HIERARCHIES
Marc Light Nov. 1993 32 p
(Contract N00014-92-J-1512; NSF IRI-90-13160)
(TR-473) Avail: CASI HC A03/MF A01

When one works with a system that utilizes inheritance hierarchies, the following problem often arises. A new object is introduced and it must be integrated into a hierarchy; under which classes in the hierarchy should the new object be positioned? I formalize this problem for feature-based default inheritance hierarchies. Since it turns out to be NP-complete, I present an approximation algorithm for it. I show that this algorithm is efficient and look at some of the possible problematic situations for the algorithm. Although more analysis and experimentation are needed, these preliminary results show that the algorithm warrants such efforts. Author (revised)

A PRACTICAL SOFTWARE ENGINEERING CURRICULUM: A PILOT STUDY Final Report
Arun P. Gupta, Weibin Zhu, Kimberly R. Brown, and Calvin Ezell 1993 15 p
(Contract MDA972-92-J-1035)
(AD-A272781) Avail: CASI HC A03/MF A01

This project identifies a problem in software engineering instruction and some approaches to overcome it. It is advocated that a software engineer must have at least one formal course in software engineering. Further, a course containing merely the concepts is not sufficient: additional course(s) complementing the formal course are required. A streamlined sequence of courses was developed that would help achieve the goals of software engineering. This report presents the course sequence and the observations for the project. It is hoped that other institutions can benefit from this study. DTIC

ADVICE FROM NONADAPTIVE QUERIES TO NP
Yenjo Han and Thomas Thierauf (Ulm Univ., Germany.) Oct. 1993 14 p
(Grants NSF CCR-89-57604; NSF INT-91-16781)
(TR-470) Avail: CASI HC A03/MF A01

Consider the standard model of computation to decide a language that is bounded truth-table reducible to an NP set: on a given input, a polynomial-time Turing machine, called a generator, produces a constant number of queries to the NP oracle; then, a second polynomial-time Turing machine, called an evaluator, given the answers to the queries, determines the membership of the given input. In this paper, we investigate the classes of languages that are decided by bounded truth-table reductions to an NP set in which evaluators do not have full access to the answers to the queries but get only partial information such as the number of queries that are in the oracle set or even just this number modulo some constant. We also investigate the case in which evaluators are nondeterministic. We locate all these classes within levels of the boolean hierarchy, which allows us to compare the complexity of such classes. The result shows the various degrees to which the power of P or NP evaluators are affected as the partial information that the evaluators get from the answers to the queries produced by generators are changed. IMAGE DETECTION USING EDGE EXTRACTION ALGORITHMS Final Report, Sep. 1991 - Aug. 1992
Chein-I Chang Aug. 1993 74 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAA15-91-K-0002)
(AD-A272439) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Alternative time-domain image detection techniques that do not require statistical models are investigated. Two distinct methods are presented; multistage pulse code modulation (MPCM) and relative entropy-based image thresholding technique. The idea of MPCM is to expand the commonly used Pulse Code Modulation (PCM) to multistage quantization to decompose an image into multiple stages. Each stage represents an image description with different details. By virtue of this decomposition, MPCM can be regarded as a progressive edge detection technique and a top-down gray-level triangle method, respectively. For vapor cloud detection, interest is often in the detection of clouds. Without reconstructing the original image, progressive edge detection extracts edges of objects progressively from the most significant contours to the least important boundaries. The relative entropy-based approach adopts a different philosophy. It utilizes a co-occurrence matrix to efficiently segment objects from the background. It chooses an information theoretic criterion relative entropy as a thresholding technique which turns out to be a better approach than existing entropic thresholding methods in most test images. METHOD FOR DESIGN ROTATION Final Report, Dec. 1991 - Jun. 1992
Ronald B. Crosier Aug. 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272440; ERDEC-TR-099) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

All rotations of a response surface design can be obtained by making planar rotations in the set of planes defined by every pair of the coordinate axes. Standard multivariate optimization routines may then be used to optimize a criterion for the desirability of a rotation as a function of the set of planar angles. Criteria for the symmetry of the design (such as the same set of factor levels for all factors) and for the size of the design region (changed by rescaling after the rotation) are developed. The hexagon design, the two-factor central composite design, the four-factor complex number design of Hardin and Sloan, and the eight-factor uniform shell design are rotated to obtain a larger region, a symmetric treatment of the factors, or both. AN INVESTIGATION INTO THE STATE OF THE PRACTICE OF CASE TOOL INTEGRATION Final Report

Jock Radar, Alan W. Brown, and Ed Morris Aug. 1993 35 p

(Contract F19628-90-C-0003)

(AD-A272441; CMU/SEI-93-TR-15; ESC-TR-93-192) Avail: CASI HC A03/MF A01

In the second half of 1992, a team of the SEI CASE Environments Project conducted a study into the state of the practice with respect to the operational use of integrated Computer-Aided Software Engineering (CASE) tools. After many false starts, a number of examples of large organizations with integrated CASE tools in operational use on software development projects were interviewed. Compared to the state of the art described in much of the literature, what was found might be considered modest. Compared to industry norms, it was quite impressive, representing significant commitment, ingenuity, and significant attention to end user needs. Our observations are detailed and the current state of the practice of CASE tool integration is analyzed. It also speculates on reasons for the modest state of the CASE tools. DTIC

FAST MUTUAL EXCLUSION, EVEN WITH CONTENTION Technical Report

Maged M. Michael and Michael L. Scott Jun. 1993 16 p

(Contract N00014-92-J-1801)

(AD-A272947; TR-460) Avail: CASI HC A03/MF A01

The authors present a mutual exclusion algorithm that performs well both with and without contention, on machines with no atomic instructions other than read and write. The algorithm capitalizes on the ability of memory systems to read and write at both full- and half-word granularities. It depends on predictable processor execution rates, but requires no bound on the length of critical sections, performs only O(n) total references to shared memory when arbitrating among conflicting requests (rather than O(n (exp 2)) in the general version of Lamport's fast mutual exclusion algorithm), and performs only 2 reads and 4 writes (a new lower bound) in the absence of contention. We provide a correctness proof. We also investigate the utility of exponential backoff in fast mutual exclusion, with experimental results on the Silicon Graphics Iris multiprocessor and on a larger, simulated machine. With backoff in place, we find that Lamport's algorithm, our new algorithm, and a recent algorithm due to Alur and Taubenfeld all work extremely well, outperforming the native hardware locks of the Silicon Graphics machine, even with heavy contention. A GRAPHICAL USER-INTERFACE DEVELOPMENT TOOL FOR INTELLIGENT COMPUTER-ASSISTED INSTRUCTION SYSTEMS M.S. Thesis

Francius Suwono Sep. 1993 119 p

(AD-A272988) Avail: CASI HC A06/MF A01

An interactive graphical interface helps intelligent computer-assisted instruction systems, because many applications can be well represented by graphic objects. One approach is a facility whereby a teacher constructing a tutor can associate specific graphics with specific predicate-calculus expressions describing a state in a tutoring simulation. This further requires a specification of the arrangement of graphic objects on the screen, how graphic objects can change position with simulation states. It also requires a language for teachers to specify graphic objects. This thesis addresses both. We introduce a broader applications of cartoon animation modelling ideas to tutoring, that have been limited so far by the complexity of their implementation. The special tools provided help computer-inexperienced instructors to develop their own cartoon animation modelling tutor without the need of mathematical description of shapes or activities to be represented. The tutor generator used employes means-ends analysis, and the language for the teachers is built using Prowindows, a Prolog extension for object-oriented design. DTIC

SELECTIVITY: REDUCTIONS, NONDETERMINISM, AND FUNCTION CLASSES

Lane A. Hemaspaandra, Albrecht Hoene (Technische Univ., Berlin, Germany.), Ashish V. Naik (State Univ. of New York, Buffalo.), Mitsunori Ogiwara (University of Electro-Communications, Tokyo, Japan.), Alan L. Selman (State Univ. of New York, Buffalo.), Thomas Thierauf (Ulm Univ., Germany.), and Jie Wang (North Carolina Univ., Greensboro.) Aug. 1993 43 p

(Grants NSF CCR-89-57604; NSF INT-91-16781; NSF CCR-90-02292; NSF CCR-91-08899)

(TR-469) Avail: CASI HC A03/MF A01

A set is P-selective if there is a polynomial-time semi-decision algorithm for the set - an algorithm that given any two strings decides which is 'more likely' to be in the set. Two natural generalizations of P-selectivity are studied: the NP-selective sets and the sets reducible or equivalent to P-selective sets via polynomial-time reductions. A strict hierarchy among the various reductions and equivalences to P-selective sets is established. It is shown that the NP-selective sets are in (NP intersect coNP)/poly, are extended low, and (those in NP) are Low(sub 2); it is also shown that NP-selective sets cannot be NP-complete unless NP = coNP. By studying more general notions of nondeterministic selectivity, it is concluded that all multivalued NP functions have single-valued NP refinements only if the polynomial hierarchy collapses to its second level. THRESHOLD COMPUTATION AND CRYPTOGRAPHIC SECURITY

Yenjo Han, Lane A. Hemaspaandra, and Thomas Thierauf (Ulm Univ., Germany.) Jun. 1993 29 p

(Grants NSF CCR-89-57604; NSF CCR-90-57486; NSF INT-91-16781)

(TR-461) Avail: CASI HC A03/MF A01

Threshold machines are Turing machines whose acceptance is determined by what portion of the machine's computation paths are accepting paths. Probabilistic machines are Turing machines whose acceptance is determined by the probability weight of the machine's accepting computation paths. Simon proved that for unbounded-error polynomial-time machines these two notions yield the same class, PP. Perhaps because Simon's result seemed to collapse the threshold and probabilistic modes of computation, the relationship between threshold and probabilistic computing for the case of bounded error has remained unexplored. In this paper, we compare the bounded-error probabilistic class BPP with the analogous threshold class, BPP(sub path), and, more generally, we study the structural properties of BPP(sub path). We prove that BPP(sub path) contains both NP(sup BPP) and P(sup NP(log)), and that BPP(sub path) is contained in P(exp summation from 2 to p of (log)), BPP(sup NP), and PP. We conclude that, unless the polynomial hierarchy collapses, bounded-error threshold computation is strictly more powerful than bounded-error probabilistic computation. We also consider the natural notion of secure access to a database: an adversary who watches the queries should gain no information about the input other than perhaps its length. We show, for both BPP and BPP(sub path), that if there is any database for which this formalization of security differs from the security given by oblivious database access, then P does not equal PSPACE. It follows that if any set lacking small circuits can be securely accepted, then P does not equal PSPACE.

A RESPONSE TO CHERITON AND SKEEN'S CRITICISM OF CASUAL AND TOTALLY ORDERED COMMUNICATION

Ken Birman Oct. 1993 33 p

(Contract N00014-92-J-1866)

(AD-A271486; CU-CSD-TR-93-1390) Avail: CASI HC A03/MF A01

In a paper to be presented at the 1993 ACM Symposium on Operating Systems Principles, Cheriton and Skeen offer their understanding of causal and total ordering as a communication property. I find their paper highly critical of Isis, and unfairly so, for a number of reasons. I present some responses to their criticism, and also explain why I find their discussion of causal and total communication ordering to be distorted and incomplete.

BEHAVIOURAL SEMANTICS OF PARALLEL FUNCTIONAL PROGRAMMING LANGUAGES
Duco Fijma 21 Oct. 1992 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Memo-INF-92-66; ETN-93-94108) Copyright Avail: CASI HC A03

The possibilities for using functional programming languages in the process of designing parallel algorithms are discussed. For this application of functional languages, the idea of 'independence of subtasks' must be formalized. This is done by presenting the behavioral semantics of such languages. This is done using a framework based on partially ordered sets of events. Annotations to express parallelism in functional languages are presented. The semantics of these annotations are defined using the same framework.

THE MERCURY USER'S MANUAL
Leonidas Kontothanassis Aug. 1993 20 p
(TR-465) Avail: CASI HC A03/MF A01

It is common for parallel applications to require a large number of threads of control, often much larger than the number of processors provided by the underlying hardware. Using heavyweight (Unix style) processes to implement those threads of control is prohibitively expensive. Mercury is an environment for writing object-oriented parallel programs in C++ that provides the user with simple primitives for inexpensive thread creation and blocking and spinning synchronization. If required, Mercury primitives allow the user to control scheduling decisions in order to achieve good locality of reference in non uniform memory access (NUMA) multiprocessors. The basic Mercury primitives are described and examples of their use are provided.

BETA(SUB k)-COMPLETE PROBLEMS AND GREEDINESS
Robert Szelepcsenyi May 1993 26 p
(Grant NSF CCR-89-57604)
(TR-455) Avail: CASI HC A03/MF A01

Kintala and Fischer defined the limited nondeterminism hierarchy within NP, the so-called beta hierarchy. Beta(sub k) is the class of languages recognized by polynomial time bounded Turing machines making at most O(log(sup k) n) nondeterministic moves, where n is the length of the input. It was conjectured that 'By restricting the amount of nondeterminism in NP-complete problems, we do not seem to obtain complete problems for beta(sub k).' It was demonstrated that this statement is incorrect under what seems to us to be the natural interpretation of the term 'restricting the amount of nondeterminism.' The concept of limited nondeterminism-preserving reductions was developed and complete problems for beta(sub k) were obtained by restricting the amount of nondeterminism in NP-complete problems. The connections between beta hierarchy completeness and greedy algorithms were discussed; it was shown that using greediness we can define many complete problems for beta.

SOME EXTENSIONS OF THE k-MEANS ALGORITHM FOR IMAGE SEGMENTATION AND PATTERN CLASSIFICATION Memorandum Report
Jose L. Marroquin and Federico Girosi Jan. 1993 22 p
(Contracts N00014-91-J-1270; N00014-92-J-1879; N00014-91-J-4038; NSF ASC-92-17041)
(AD-A271691; AI-M-1390) Avail: CASI HC A03/MF A01

In this paper we present some extensions to the k-means algorithm for vector quantization that permit its efficient use in image segmentation and pattern classification tasks. It is shown that by introducing state variables that correspond to certain statistics of the dynamic behavior of the algorithm, it is possible to find the representative centers of the lower dimensional manifolds that define the boundaries between classes, for clouds of multi-dimensional, multi-class data; this permits one, for example, to find class boundaries directly from sparse data (e.g., in image segmentation tasks) or to efficiently place centers for pattern classification (e.g., with local Gaussian classifiers). The same state variables can be used to define algorithms for determining adaptively the optimal number of centers for clouds of data with space-varying density. Some examples of the application of these extensions are also given.

DATA AND MODEL-DRIVEN SELECTION USING PARALLEL-LINE GROUPS Memorandum Report
Syeda-Tanveer F. Mahmood May 1993 31 p
(Contracts N00014-91-J-4038; DACA76-85-C-0010; NSF IRI-89-00267)
(AD-A271702; AI-M-1399) Avail: CASI HC A03/MF A01

A key problem in model-based object recognition is selection, namely, the problem of isolating regions in an image that are likely to come from a single object. This isolation can be either based solely on image data (data-driven) or can incorporate the knowledge of the model object (model-driven). In this paper we present an approach that exploits the property of closely-spaced parallelism between lines on objects to achieve data and model-driven selection. Specifically, we present a method of identifying groups of closely-spaced parallel lines in images that generates a linear number of small-sized and reliable groups thus meeting several of the desirable requirements of a grouping scheme for recognition. The line groups generated form the basis for performing data and model-driven selection. Data-driven selection is achieved by selecting salient line groups as judged by a saliency measure that emphasizes the likelihood of the groups coming from single objects. The approach to model-driven selection, on the other hand, uses the description of closely-spaced parallel line groups on the model object to selectively generate line groups in the image that are likely to be the projections of the model groups under a set of allowable transformations and taking into account the effect of occlusions, illumination changes, and imaging errors. We then discuss the utility of line groups-based selection in the context of reducing the search involved in recognition, both as an independent selection mechanism, and when used in combination with other cues such as color. Finally, we present results that indicate a vast improvement in the performance of a recognition system that is integrated with parallel line groups-based selection.

USE OF COMPUTERS IN THE INSTRUCTION OF INTEGRAL CALCULUS M.S. Thesis
Dennis A. Polaski Mar. 1993 165 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272500) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

One of the most difficult concepts in the area of integral multivariate calculus is finding the limits of integration. This thesis describes an interactive computer program designed to help students understand this important concept. The program shows how a given domain is plotted and teaches how to find the limits of integration when evaluating two-dimensional integrals. The program allows the user to enter any known information about a region and then evaluates the integral. The region is plotted; the limits of integration are given along with the area of the region. The program handles cartesian and polar coordinate, two-dimensional integral problems. This program could be used independently by the student and/or used by the calculus instructor in the classroom.

MAYGEN: A SYMBOLIC DEBUGGER GENERATION SYSTEM
Christine L. Tsien Jul. 1993 86 p
(Contract N00014-91-J-4038)
(AD-A272512; AI-TR-1429) Avail: CASI HC A05/MF A01

With the development of high-level languages for new computer architectures comes the need for appropriate debugging tools as well. One

method for meeting this need would be to develop, from scratch, a symbolic debugger with the introduction of each new language implementation for any given architecture. This, however, seems to require unnecessary duplication of effort among developers. Compilation technology has alleviated some duplication of effort in the development of compilers. Can similar ideas aid in the efficient development of symbolic debuggers as well? Maygen explores the possibility of making debugger development efficient by influencing the language and architecture development processes. Maygen is a debugger generation system, built upon the idea that symbolic debuggers can be divided into three components: a set of source language interface routines, a set of machine architecture interface routines, and a language-independent and architecture-independent debugger skeleton. Maygen then exploits this modularity: First, Maygen precisely defines as well as houses the language-independent and architecture-independent debugger skeleton. Second, Maygen defines the protocol for interface interaction among source language developers, machine architecture developers, and the general-purpose debugger skeleton. Finally, Maygen provides a framework in which the resident debugger skeleton is automatically developed into a stand-alone symbolic debugger; the resulting debugger is tailored to the specific provisions of a particular language group and a particular architecture group. THE TERM PROCESSOR KIMWITU MANUAL AND COOKBOOK
Peter vanEijk and Axel Belinfante 1992 51 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Memo-INF-92-67; TIOS-92/28; ETN-93-94109) Copyright Avail: CASI HC A04

A system that supports the construction of programs that use 'trees' or 'terms' as their main data structure is described. This system is a 'meta' tool in the development process of tools. Its 'input' is an abstract description of terms, annotated with implementation directives, plus a description of functions on these terms. The 'output' consists of a number of C-files that contain data structure definitions for the terms, a number of standard functions on those terms, and a translation (in C) of the function definitions in the input (for example, term rewriting). The standard functions can be used to create terms, compare them for equality, read and write them on files in various formats and do manipulations like list concatenation. The input format of the term processor is described and the output of the system is described: the C types and functions, the files, etc. The running of the system, and the relation with other software development tools, such as the UNIX tools make, yacc, lex, lint, and the Synthesizer Generator are detailed. Various techniques in which programs can be written over terms are discussed, thus giving examples of the concept of 'multi paradigm programming'. ESA

A MULTI-LEVEL SOLUTION ALGORITHM FOR STEADY-STATE MARKOV CHAINS
Graham Horton (Erlangen-Nuremberg Univ., Germany.) and Scott T. Leutenegger Nov. 1993 32 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191558; ICASE-93-81; NAS 1.26:191558) Avail: CASI HC A03/MF A01

A new iterative algorithm, the multi-level algorithm, for the numerical solution of steady state Markov chains is presented. The method utilizes a set of recursively coarsened representations of the original system to achieve accelerated convergence. It is motivated by multigrid methods, which are widely used for fast solution of partial differential equations. Initial results of numerical experiments are reported, showing significant reductions in computation time, often an order of magnitude or more, relative to the Gauss-Seidel and optimal SOR algorithms for a variety of test problems. The multi-level method is compared and contrasted with the iterative aggregation-disaggregation algorithm of Takahashi. Author (revised)

PROCEDURAL DYNAMIC SEMANTICS, VERB-PHRASE ELLIPSIS, AND PRESUPPOSITION
D. Jan N. vanEijck (OTS, Utrecht, Netherlands.) and Nissim Francez (Technion - Israel Inst. of Tech., Haifa.) Feb. 1993 17 p Sponsored in part by Technion - Israel Inst. of Tech. and Haifa Univ. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-CS-R9311; ETN-94-94740) Copyright Avail: Issuing Activity (European Space Agency (ESA))

Verb Phrase Ellipsis (VPE) is studied and its relationship to presupposition and its failure is shown. A representation of VPE by means of a dynamic semantics approach is used, using an extended version of Dynamic Predicate Logic which includes procedures, scope rules and functions. Focus is on the representation of the strict/sloppy ambiguity in connection with ellipsis constructs, which comes 'for free' in a procedural context. Independent justification for the representation of VPE in terms of procedure definitions and their invocations is provided. The relationship of VPE and presupposition sheds light on the arguments about the question whether VPE is syntactic or semantic in nature, as well as on the relative order of meaning determination and presupposition determination. Part of a larger scale enterprise to pursue the obvious parallel between information processing and imperative programming is presented. Logical tools from theoretical computer science are demonstrated to be relevant for the logic of information flow. More specifically, it is shown that the perspective of Hoare logic can be aplied to the conceptual simplification of information flow logics. In conclusion, it is argued that interpreting the dynamic statements of information logics as dynamic modal operators has much wider applicability. In fact, the method can be used to axiomatize quite a wide range of information logics. ESA

COMPUTING WITH BAYESIAN MULTI-NETWORKS
Eugene Santos, Jr. 16 Nov. 1993 18 p
(AD-A273106; AFIT/EN/TR93-10) Avail: CASI HC A03/MF A01

Existing probabilistic approaches to automated reasoning impose severe

restrictions on its knowledge representation scheme. Mainly, this is to ensure that there exists an effective inferencing algorithm. Unfortunately, this makes the application of these approaches to general domains quite difficult. In this paper, we present a new model called Bayesian multi-networks which uses a rule-based organization of knowledge quite natural for human experts modeling various domains. Furthermore, strong probabilistic semantics help quantify the knowledge. Combined with the rich structure of rule-based approaches, a general inference engine for Bayesian multi-networks is developed. DTIC

MINIFOLD: A KERNEL FOR A MANIFOLD-LIKE COORDINATION LANGUAGE

E. P. B. M. Rutten Dec. 1992 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(CWI-CS-R9252; ETN-94-94732) Copyright Avail: CASI HC A03

MINIFOLD is a kernel for a coordination language, following the MANIFOLD model. This model focuses on the coordination of processes, separated from their computation functionality. Processes are considered as black boxes, and their behavior is abstracted to their communications. MINIFOLD provides constructs to build up an environment of concurrent processes and to manage the communication between them. On one hand, a data flow mechanism can be used to build networks of streams, linking input and output ports of the processes, and carrying the units exchanged between them. On the other hand, an event broadcasting mechanism provides control on the dynamical modification of the data flow network. MINIFOLD is introduced in a constructive and incremental way. It is provided with an operational semantics; a model of its execution based on automata is proposed and illustrated by simple classical example. A study to explore models of the behavior of the MANIFOLD concept and to formalize its bare essentials is presented. It is intended that the MANIFOLD language can take advantage of this, as guidelines for formalisms underlying practical tools for program analysis, clarification of its structure and a basis for the comparison with other models. A LOWER BOUND ON WAIT-FREE COUNTING

Shlomo Moran (Technion - Israel Inst. of Tech., Haifa.) and Gadi Taubenfeld (Bell Telephone Labs., Inc., Murray Hill, NJ.) Feb. 1993 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(CWI-CS-R9307; ETN-94-94736) Copyright Avail: CASI HC A03

A counting protocol (mod m) consists of shared memory bits, referred to as the counter, and a procedure for incrementing the counter value by one (mod m). The procedure may be executed by many processes concurrently. It is required to satisfy a very weak correctness requirement, namely: the counter is required to show a correct value only in quiescent states (states in which no process is incrementing the counter). Special cases of counting protocols are 'counting networks' and 'concurrent counters.' The problem of implementing a wait-free counting protocol, assuming that the basic atomic operation of a process is a read-modify-write on a single bit, is considered. Let flip(Pr) be the maximum number of times a single increment operation changes the counter bits in a counting protocol Pr. The main result is: in any wait-free counting protocol Pr which counts modulo m, m divides 2(exp flip(Pr)). Thus, flip(Pr) is greater than or equal to log m and m is a power of two. This result provides interesting generalizations of lower bounds and impossibility results for counting and smoothing networks. ESA

COUPLING OF SMOOTH PARTICLE HYDRODYNAMICS WITH PRONTO

S. W. Attaway, M. W. Heinstein, F. J. Mello, and J. W. Swegle 1993 12 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993

(Contract DE-AC04-76DP-00789)

(DE93-019080; SAND-93-1781C; CONF-931121-17) Avail: CASI HC A03/MF A01

A gridless numerical technique called smooth particle hydrodynamics (SPH) has been coupled to the transient dynamics finite element code, PRONTO. In this paper, a new weighted residual derivation for the SPH method is presented, and the methods used to embed SPH within PRONTO are outlined. Example SPH-PRONTO calculations are also presented. One major difficulty associated with the Lagrangian finite element method is modeling materials with no shear strength; for example, gases, fluids and explosive bi-products. Typically these materials can be modeled for only a short time with a Lagrangian finite element code. Large distortions cause tangling of the mesh, which will eventually lead to numerical difficulties such as negative element area or 'bow tie' elements. Remeshing will allow the problem to continue for a short while, but the large distortions can prevent a complete analysis. Smooth particle hydrodynamics is a gridless Lagrangian technique. Requiring no mesh, SPH has the potential to model material fracture, large shear flows, and penetration. SPH computes the strain rate and the stress divergence based on the nearest neighbors of a particle, which are determined using an efficient particle sorting technique. Embedding the SPH method within PRONTO allows part of the problem to be modeled with quadrilateral finite elements while other parts are modeled with the gridless SPH method. SPH elements are coupled to the quadrilateral elements through a contact like algorithm. DOE

An exploratory document for research in logical semantics emerging from several current developments in computer science is presented. Standard logic employs 'flat' unstructured sets of statements for its theories and unstructured classes of models for its semantic universes. Nowadays, however, there is an incipient literature on structured universes of models as well as structured theories, both employing 'preference relations', of some sort. This report aims: to propose a more systematic framework for this trend, while also connecting it up with some historical predecessors; to design some new logical systems bringing preferences out explicitly, thereby highlighting the theoretical properties of 'preferential reasoning' while raising some new kinds of technical question for further research; to link up with some current computational ideas (emerging also in the field of linguistics), by bringing in the general dynamic logic of procedures as well as logical systems providing suitable fine structure of information states. USING PARALLEL BANDED LINEAR SYSTEM SOLVERS IN GENERALIZED EIGENVALUE PROBLEMS Final Report

Hong Zhang (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.) and William F. Moss (Clemson Univ., SC.) Sep. 1993 20 p Submitted for publication

(Contract NAS1-19480; NSF CCR-91-03296; RTOP 505-90-52-01)

(NASA-CR-191540; NAS 1.26:191540; ICASE-93-71) Avail: CASI HC A03/MF A01

Subspace iteration is a reliable and cost effective method for solving positive definite banded symmetric generalized eigenproblems, especially in the case of large scale problems. This paper discusses an algorithm that makes use of two parallel banded solvers in subspace iteration. A shift is introduced to decompose the banded linear systems into relatively

independent subsystems and to accelerate the iterations. With this shift, an eigenproblem is mapped efficiently into the memories of a multiprocessor and a high speed-up is obtained for parallel implementations. An optimal shift is a shift that balances total computation and communication costs. Under certain conditions, we show how to estimate an optimal shift analytically using the decay rate for the inverse of a banded matrix, and how to improve this estimate. Computational results on iPSC/2 and iPSC/860 multiprocessors are presented. Author

TERMINATION AND CONFLUENCE OF RULE EXECUTION
M. H. Leonie vanderVoort and Arno P. J. M. Siebes Feb. 1993 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-CS-R9309; ETN-94-94738) Copyright Avail: CASI HC A03

A design theory for rule sets in an OODBMS (Object Oriented Data Base Management System) is developed. Two predicates, Terminate(n) and Independent, which imply respectively termination and confluency, are introduced. Both predicates are characterized under two kinds of rule execution semantics: set and instance based. The decidability of the predicates is proven and it is shown that set and instance based semantics coincide whenever the rule set is independent and terminates. Sufficient conditions of low algorithmic complexity for both Terminate(n) and Independent under both kinds of semantics are given. ESA

ADVANCED FAILURE ANALYSIS LABORATORY EQUIPMENT NETWORKING
C. L. Henderson and D. L. Barton 1993 9 p Presented at the 1993 Integrated Diagram Systems Users Conference, San Jose, CA, 24-26 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019070; SAND-93-1748C; CONF-9308146-1) Avail: CASI HC A02/MF A01

Today's integrated circuits are so complex that it is often necessary to have access to the layouts and schematics when performing voltage contrast, cross sectioning, light emission, mechanical probing, optical beam induced current, and even simple SEM and Optical Examination. To deal with these issues, Sandia National Laboratories is developing an advanced failure analysis laboratory networking scheme to provide computer control, layout navigation, schematic navigation, and report generation on each of the major pieces of failure analysis equipment. This concept is known as an Integrated Diagnostic Environment or IDE. An integrated diagnostic environment is an environment where failure analysis equipment is computer-controlled and linked by a high speed network. The network allows CAD databases to be shared between instruments, improving the failure analyst's productivity on each analysis task. At Sandia, we are implementing this concept using SUN Sparcstation computers running Schlumberger's IDE software. To date, we have incorporated our electron beam prober and light emission system into the environment. We will soon add our scanning optical microscope and focused ion beam system and eventually add our optical microscope and microprobe station into the network. There are a number of issues to consider when implementing an Integrated Diagnostic Environment; these are discussed in detail. DOE

RHALE: A 3-D MMALE CODE FOR UNSTRUCTURED GRIDS
J. S. Peery, K. G. Budge, M. K. W. Wong, and T. G. Trucano 1993 16 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019405; SAND-93-0178C; CONF-931121-19) Avail: CASI HC A03/MF A01

RHALE, a multi-material arbitrary Lagrangian-Eulerian (MMALE) shock physics code, is described. RHALE is the successor to CTH, Sandia's 3-D Eulerian shock physics code, and will be capable of solving problems that CTH cannot adequately address. The Lagrangian solid mechanics capabilities of RHALE, which include arbitrary mesh connectivity, superior artificial viscosity, and improved material models, are discussed. The MMALE algorithms that were extended for arbitrary grids in both two- and three-dimensions are discussed. The MMALE addition to RHALE provides the accuracy of a Lagrangian code while allowing a calculation to proceed under very large material distortions. Coupling an arbitrary quadrilateral or hexahedral grid to the MMALE solution facilitates modeling of complex shapes with a greatly reduced number of computational cells. RHALE allows regions of a problem to be modeled with Lagrangian, Eulerian or ALE meshes. In addition, regions can switch from Lagrangian to ALE to Eulerian based on user input or mesh distortion. For ALE meshes, new node locations are determined with a variety of element based equipotential schemes. Element quantities are advected with donor, van Leer, or Super-B algorithms. Nodal quantities are advected with the second order SHALE or HIS algorithms. Material interfaces are determined with a modified Young's high resolution interface tracker or the SLIC algorithm. RHALE was used to model many problems of interest to the mechanics, hypervelocity impact, and shock physics communities. Results of a sampling of these problems are presented. DOE

A METHODOLOGY FOR QUANTIFYING UNCERTAINTY IN MODELS
M. D. McKay and R. J. Beckman 1993 4 p Presented at the Surety Technology Symposum, Chelyacinsk, Russia, 28 Sep. - 2 Oct. 1993
(Contract W-7405-eng-36)
(DE93-040154; LA-UR-93-3160; CONF-9309215-1) Avail: CASI HC A01/MF A01

This paper, condensed from McKay et al. (1992) outlines an analysis of uncertainty in the output of computer models arising from uncertainty in inputs (parameters). Uncertainty of this type most often arises when proper input values are imprecisely known. Uncertainty in the output is quantified in its probability distribution, which results from treating the inputs as random variables. The assessment of which inputs are important (sensitivity analysis) with respect to uncertainty is done relative to the probability distribution of the output. DOE

STOCHASTIC SIMULATION FOR IMAGING SPATIAL UNCERTAINTY: COMPARISON AND EVALUATION OF AVAILABLE ALGORITHMS
C. A. Gotway and B. M. Rutherford 1993 21 p Presented at the Workshop in English on Geostatistical Simulations, Fontainebleau, France, 27 May 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-040058; SAND-93-0438C; CONF-9305268-1) Avail: CASI HC A03

Stochastic simulation has been suggested as a viable method for

characterizing the uncertainty associated with the prediction of a nonlinear function of a spatially-varying parameter. Geostatistical simulation algorithms generate realizations of a random field with specified statistical and geostatistical properties. A nonlinear function is evaluated over each realization to obtain an uncertainty distribution of a system response that reflects the spatial variability and uncertainty in the parameter. Crucial management decisions, such as potential regulatory compliance of proposed nuclear waste facilities and optimal allocation of resources in environmental remediation, are based on the resulting system response uncertainty distribution. Many geostatistical simulation algorithms have been developed to generate the random fields, and each algorithm will produce fields with different statistical properties. These different properties will result in different distributions for system response, and potentially, different managerial decisions. The statistical properties of the resulting system response distributions are not completely understood, nor is the ability of the various algorithms to generate response distributions that adequately reflect the associated uncertainty. This paper reviews several of the algorithms available for generating random fields. Algorithms are compared in a designed experiment using seven exhaustive data sets with different statistical and geostatistical properties. For each exhaustive data set, a number of realizations are generated using each simulation algorithm. The realizations are used with each of several deterministic transfer functions to produce a cumulative uncertainty distribution function of a system response. The uncertainty distributions are then compared to the single value obtained from the corresponding exhaustive data set. DOE

GEOMETRIC OPTIMIZATION
P. Hinker and C. Hansen 1993 8 p Presented at the Visualization 1993, San Jose, CA, 25-29 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(Contract W-7405-eng-36)
(DE93-040152; LA-UR-93-3140; CONF-931080-4) Avail: Issuing Activity (Department of Energy (DOE))

An algorithm is presented which describes an application independent method for reducing the number of polygonal primitives required to faithfully represent an object. Reducing polygon count without a corresponding reduction in object detail is important for: achieving interactive frame rates in scientific visualization, reducing mass storage requirements, and facilitating the transmission of large, multi-timestep geometric data sets. This paper shows how coplanar and nearly coplanar polygons can be merged into larger complex polygons and re-triangulated into fewer simple polygons than originally required. The notable contributions of this paper are: (1) a method for quickly grouping polygons into nearly coplanar sets, (2) a fast approach for merging coplanar polygon sets, and (3) a simple, robust triangulation method for polygons created by (1) and (2). The central idea of the algorithm is the notion of treating polygonal data as a collection of segments and removing redundant segments to quickly form polygon hulls which represent the merged coplanar sets. IMAGING VECTOR FIELDS USING LINE INTEGRAL CONVOLUTION
B. Cabral and L. C. Leedom 1 Mar. 1993 10 p Presented at the Computer Graphics (CG) Conference, Anaheim, CA, 1-6 Aug. 1992
(Contract W-7405-eng-48)
(DE93-019922; UCRL-JC-112935; CONF-9208240-1) Avail: CASI HC A02/MF A01

Imaging vector fields has applications in science, art, image processing, and special effects. An effective new approach is to use linear and curvilinear filtering techniques to locally blur textures along a vector field. This approach builds on several previous texture generation and filtering techniques. It is, however, unique because it is local, one-dimensional, and independent of any predefined geometry or texture. The technique is general and capable of imaging arbitrary two- and three-dimensional vector fields. The local one-dimensional nature of the algorithm lends itself to highly parallel and efficient implementations. Furthermore, the curvilinear filter is capable of rendering detail on very intricate vector fields. Combining this technique with other rendering and image processing techniques--like periodic motion filtering--results in richly informative and striking images. The technique can also produce novel special effects. DOE

SURVEY AND ALIGNMENT ANALYSIS FOR THE ALS STORAGE RING USING COMPUTER SPREADSHEETS
R. Keller Jul. 1993 11 p Presented at the 3rd International Workshop on Accelerator Alignments, Annecy, France, 28 Sep. - 1 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC03-76SF-00098)
(DE93-019254; LBL-34335; LSGN-143; CONF-9309204-2) Avail: CASI HC A03

The general survey and alignment concept for the ALS is based on a network of fixed, three-dimensional monuments installed in the building floor, to which all accelerator component positions are referred. The survey of these monuments is performed separately for horizontal and vertical coordinates, following the scheme imposed by the code PC-GEONET that is used for monument data analysis. For most of the accelerator objects the tasks of data acquisition, bundling, and transformations from observation-station into object coordinate-systems are being handled by the commercial software package ECDS rather than by PC-GEONET. This choice had to be made because no instrument stands are presently available at LBL that can be placed exactly over monuments and are high enough to permit observing the fiducials of installed magnets from above. Theodolites only are used with ECDS as observation instruments, and absolute scaling has to be provided by observing some object of precisely known length. To create ideal data and compute alignment values for all accelerator components, spreadsheets were developed by the author using the application EXCEL for Macintosh computers. Choice of a spreadsheet method rather than conventional programming techniques proved very convenient when in the course of this work the sheets had to be created and progressively modified under severe time pressure to include new effects and help redefine the observation procedures. With spreadsheets, varying input data formats coming from the survey crew could be easily accommodated, and adding numerous consistency checks as well as generating additional ideal data for special alignment tasks was possible with comparatively little effort. Dedicated spreadsheets were created for each of the 12 curved sectors of the storage ring. In this paper, the main features of the spreadsheets are presented, and the alignment results for lattice and corrector magnets are listed and discussed. DOE

USER'S GUIDE FOR THE CASTING PROCESS SIMULATOR SOFTWARE CaPS-2D, VERSION 1.0
H. M. Domanus, R. C. Schmitt, and S. Ahuja Jul. 1993 104 p
(Contract W-31-109-eng-38)
(DE93-040398; ANL-93/14) Avail: CASI HC A06/MF A02

Most casting defects occur during initial pouring and therefore the design of the running system, which guides the metal from the ladle into the mold, is crucial. Traditionally, the running system and mold filling are designed by trial and error, which is tedious, time consuming, and expensive.

The uncertainties that remain can be overcome by a computer simulation that demonstrates the actual process of mold filling and subsequent solidification. Computer simulation of various processes has become more and more common in recent years. The cost-effectiveness of making flawless castings has made the foundry worker more aware of the process of mold filling, identification of hot spots, etc. The macroscopic Casting Process Simulator (CaPS) software combines heat transfer and fluid flow aspects and can describe a variety of solidification aspects, including mold filling. CaPS is a two-dimensional time-dependent computer code involving a finite volume formulation for the mass, momentum, and energy equations. CaPS has the following characteristics: CaPS uses the PATRAN geometric modeling package for constructing the geometry, generating a neutral file consisting of a list of named components, and post-processing of the simulation results; building the geometry independently of the mesh is a time-saving procedure. A structured mesh generator of structured regular cells is included and is interfaced with the neutral-file output of the solid geometric package. Visual user interfaces have been developed on the basis of the HOOPS package, which contains a hierarchical database of geometric information. The CaPS shell scripts interactively provide a step-by-step procedure to simulate the solidification process, thus making the software very user-friendly. DOE

AN EVALUATION OF INTEGRATION OF THE TRACE ASSERTION METHOD WITH THE BOX STRUCTURE METHOD FOR CODING IN C++
A. L. Bangs Aug. 1993 197 p
(Contract DE-AC05-84OR-21400)
(DE93-040480; ORNL/TM-12439) Avail: CASI HC A09/MF A03

The trace assertion method is a method for developing specifications for software modules. The nature of the method allows verification of consistency and completeness of the specification and provides a rigid structure to the designer. This method is extended to work with object-oriented designs for a C++ system involving a user interface. A number of object-oriented concepts which are not present in the original trace assertion method are incorporated into the method and demonstrated on two completely specified increments of the system being developed. In addition, the method is incorporated into a system wide view beyond the original modular scope of the method. Advantages of the adapted method and its problems are discussed. DOE

ENHANCED SOFTWARE FOR THE GT1022 AUTOMATED GAGING SYSTEM
R. E. Hines Sep. 1993 28 p
(Contract DE-AC04-76DP-00613)
(DE94-001374; KCP-613-5153) Avail: CASI HC A03/MF A01

Several enhancements have been added to the gaging software of a microcomputer-controlled gaging system (GT1022) that is used to acquire and process dimensional product data from multiprobe rotary gages. Processing routines have been developed to inspect five additional feature types: dimension, least squares center, MMC position with datum diameter bonus, total indicator reading, and two-sided wall thickness. Mathematical alignment routines have been added that permit parts to be gaged in a misaligned condition and then have the measurements corrected relative to the part's datum axes. DOE

REVERSE AUTOMATIC DIFFERENTIATION OF MODULAR FORTRAN PROGRAMS
J. E. Horwedel 1993 5 p Presented at the Theory Institute on Combinatorial Challenges in Computational Differentiation Workshop, Argonne, IL, 24-26 May 1993
(Contract DE-AC05-84OR-21400)
(DE94-000336; CONF-9305285-1) Avail: CASI HC A01/MF A01

The calculation of derivatives necessary for sensitivity analysis or for the optimal solution of systems of nonlinear equations continues to be an important research objective. Several software systems were developed for implementing automatic differentiation of computer programs. The forward mode of automatic differentiation is efficient for calculating derivatives for a large number of dependent variables with respect to a few independent variables. As the number of independent variables increases, the computational complexity, as measured in execution time and memory requirements, renders the forward mode impractical. The reverse mode or adjoint approach is efficient for derivatives of a few dependent variables with respect to thousands of independent variables; however, available memory and disk storage generally limit the application of the reverse mode to problems with less than a few million floating point assignments. The fundamental problem with the reverse mode of automatic differentiation is that the accumulation of derivatives is required. A code that uses 3 minutes of execution time to perform 50 million floating point assignments could easily need more than one gigabyte to store the accumulated derivatives. DOE

ALGORITHMS FOR MARKOV DECISION CHAINS WITH PARTIAL INFORMATION
J. A. Loeve 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-220085; TW-92-14) Avail: Issuing Activity (National Technical Information Service (NTIS))

In this paper, the author considers Markov decision chains with partial state information. This means that the state space is partitioned, and at each decision moment the only information available on the state of the system is in which set of the partition it is contained. So the exact state is not known. The author presents several algorithms for this model. The author analyzes these and applies them on several examples, in particular on a special queueing model. Computational fluid dynamics applications of grid research at LRC include inlets, nozzles, and ducts; turbomachinery; propellers - ducted and unducted; and aircraft icing. Some issues related to internal flow grid generation are resolution requirements on several boundaries, shock resolution vs. grid periodicity, grid spacing at blade/shroud gap, grid generation in turbine blade passages, and grid generation for inlet/nozzle geometries. Aircraft icing grid generation issues include (1) small structures relative to airfoil chord must be resolved; (2) excessive number of grid points in far-field using structured grid; and (3) grid must be recreated as ice shape grows. This work has three objectives: to develop a three-dimensional flow solver based on unstructured tetrahedral meshes for turbomachinery flows; to validate the solver through comparisons with experimental data; and to apply the solver for better understanding of the flow through turbomachinery geometries and design improvement. The work followed three different approaches: an existing external flow solver/grid generator (USM3D/VGRID) was extensively modified for internal flows; a three-dimensional, finite-volume solver based on Roe's flux-difference splitting and explicit Runge-Kutta time stepping; and three-dimensional unstructured tetrahedral mesh generation using an advancing-front technique. A discussion of these topics is presented in viewgraph form. Derived from text

DEVELOPMENT OF A GRIDLESS CFD METHOD
John T. Batina *In its* Unstructured Grid Generation Techniques and Software Sep. 1993 p 151-162 (For primary document see N94-22350 05-61)
Avail: CASI HC A03/MF A03

The objective of this paper is to stimulate ideas concerning alternative approaches to discretizing fluid flow problems, i.e., the so-called gridless approach. The gridless approach uses only clouds of points and does not require that the points be connected to form a grid as is necessary in conventional CFD algorithms. The governing equations are solved directly by performing local least-squares curve fits in each cloud of points and then analytically differentiating the resulting curve fits to approximate the

derivatives. A discussion of these topics is presented in viewgraph form.

This paper presents in viewgraph form a method of optimizing grid generation for unsteady CFD flow calculations that distributes the numerical error evenly throughout the mesh. Adaptive meshing is used to locally enrich in regions of relatively large errors and to locally coarsen in regions of relatively small errors. The enrichment/coarsening procedures are robust for isotropic cells; however, enrichment of high aspect ratio cells may fail near boundary surfaces with relatively large curvature. The enrichment indicator worked well for the cases shown, but in general requires user supervision for a more efficient solution. CASI

Presented in viewgraph format are some of the benefits of computational geometry for grid generation, including benefits to grid quality and algorithm efficiency. Many efficient algorithms are available, but it is concluded that high aspect ratio triangulations are not among them. Derived from text

SURFACE ACQUISITION THROUGH VIRTUAL MILLING

Marshal L. Merriam *In* NASA. Langley Research Center, Unstructured Grid Generation Techniques and Software Sep. 1993 p 323-337 (For primary document see N94-22350 05-61)
Avail: CASI HC A03/MF A03

Surface acquisition deals with the reconstruction of three dimensional objects from a set of data points. The most straightforward techniques require human intervention, a time consuming proposition. It is desirable to develop a fully automated alternative. Such a method is proposed in this paper. It makes use of surface measurements obtained from a 3-D laser digitizer - an instrument which provides the (x,y,z) coordinates of surface data points from various viewpoints. These points are assembled into several partial surfaces using a visibility constraint and a 2-D triangulation technique. Reconstruction of the final object requires merging these partial surfaces. This is accomplished through a procedure that emulates milling, a standard machining operation. From a geometrical standpoint the problem reduces to constructing the intersection of two or more non-convex polyhedra.

The major SSC experiments are expected to produce up to 1 Petabyte of data per year each. Once the primary reconstruction is completed by farms of inexpensive processors, I/O becomes a major factor in further analysis of the data. We believe that the application of database techniques can significantly reduce the I/O performed in these analyses. We present examples of such I/O reductions in prototypes based on relational and object-oriented databases of CDF data samples.

The concept of providing transparent access to a collection of files in a mass storage system is a familiar one. The goal of this project was to investigate the feasibility of providing similar access to a collection of persistent, complex objects. We describe an architecture for interfacing a persistent store of complex objects to a hierarchical storage system. Persistent object stores support the uniform creation, storage, and access of complex objects, regardless of their lifetimes. In other words, a mechanism is provided so that persistent objects outlive the processes which create them and can be accessed in a uniform manner by other processes. We validated this architecture by implementing a proof-of-concept system and testing the system on two stores of data. These tests indicate that this architecture supports the creation, storage, and access of very large persistent object stores.

A COMPARISON OF IDEF1X AND NIAM ISDM
J. K. Sharp 1993 13 p Presented at the 1993 Conference on Natural Language Information Analysis Methodology and Information System Design Methodology, Utrecht, 15-17 Sep. 1993
(Contract DE-AC04-76DP-00789)
(DE93-040899; SAND-93-2130C; CONF-9309238-1) Avail: CASI HC A03/MF A01

This paper describes the major differences in the IDEFIX and NIAM ISDM information modeling methodologies and presents the different philosophies behind these methodologies. The IDEFIX methodology base document comes from the Integrated Information Support System (IISS) project sponsored by the US Air Force. The IISS project office was contacted and they supplied the referenced document as the best base description of this methodology. The NIAM ISDM methodology base documents present the general NIAM methodology. IDEFIX is a variant of the entity-attribute-relationship (E-A-R) approach to data modeling and although many other variants exist, the comparison presented here covers the common aspects of entity-relationship approaches. This comparison identifies and illustrates the differences in the two methodologies.

Practical planning problems with deterministic forecasts of inherently uncertain parameters often yield unsatisfactory solutions. Stochastic programming formulations allow uncertain parameters to be modeled as random variables with known distributions, but the size of the resulting mathematical programs can be formidable. Decomposition-based algorithms take advantage of special structure and provide an attractive approach to such problems. We consider two classes of decomposition-based stochastic programming algorithms. The first type of algorithm addresses problems with a 'manageable' number of scenarios. The second class incorporates Monte Carlo sampling within a decomposition algorithm. We develop and empirically study an enhanced Benders decomposition algorithm for solving multistage stochastic linear programs within a prespecified tolerance. The enhancements include warm start basis selection, preliminary cut generation, the multicut procedure, and decision tree traversing strategies. Computational results are presented for a collection of 'real-world' multistage stochastic hydroelectric scheduling problems. Recently, there has been an increased focus on decomposition-based algorithms that use sampling within the optimization framework. These approaches hold much promise for solving stochastic programs with many scenarios. A critical component of such algorithms is a stopping criterion to ensure the quality of the solution. With this as motivation, we develop a stopping rule theory for algorithms in which bounds on the optimal objective function value are estimated by sampling. Rules are provided for selecting sample sizes and terminating the algorithm under which asymptotic validity of confidence interval statements for the quality of the proposed solution can be verified. Issues associated with the application of this theory to two sampling-based algorithms are considered, and preliminary empirical coverage results are presented.

This paper presents the Physics Detector Simulation Facility (PDSF) Phase II system software. A key element in the design of a distributed computing environment for the PDSF has been the separation and distribution of the major functions. The facility has been designed to support batch and interactive processing and to incorporate the file and tape storage systems. By distributing these functions, it is often possible to provide higher throughput and resource availability. Similarly, the design is intended to exploit event-level parallelism in an open distributed environment. DOE

N94-19858# Sandia National Labs., Livermore, CA.
TCP PERFORMANCE ANALYSIS FOR WIDE AREA NETWORKS
H. Y. Chen, J. A. Hutchins, and N. Testi (Sandia National Labs., Albuquerque, NM.) Aug. 1993 29 p
(Contract DE-AC04-76DR-00789)
(DE94-000449; SAND-93-8243) Avail: CASI HC A03/MF A01

Even though networks have been getting faster, perceived throughput at the application level has not increased accordingly. In an attempt to identify many of the performance bottlenecks, the authors collected and analyzed data over a wide area network (WAN) at T3 (45 Mbps) bandwidth. The information gained will assist in designing new protocols and/or algorithms that are consistent with future high-speed requirements. DOE

EXPLOITING THE PARALLELISM EXPOSED BY PARTIAL EVALUATION Memorandum Report
Andrew Berlin and Rajeev J. Surati Apr. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-4093; NSF MIP-90-01651)
(AD-A270678) Avail: CASI HC A03

We describe an approach to parallel compilation that seeks to harness the vast amount of fine-grain parallelism that is exposed through partial evaluation of numerically-intensive scientific programs. We have constructed a compiler for the Supercomputer Toolkit parallel processor that uses partial evaluation to break down data abstractions and program structure, producing huge basic blocks that contain large amounts of fine-grain parallelism. We show that this fine-grain parallelism can be effectively utilized even on coarse-grain parallel architectures by selectively grouping operations together so as to adjust the parallelism grain-size to match the inter-processor communication capabilities of the target architecture. SEGMENTED OPERATIONS FOR SPARSE MATRIX COMPUTATION ON VECTOR MULTIPROCESSORS
Guy E. Blelloch, Michael A. Heroux, and Marco Zagha Aug. 1993 25 p Prepared in cooperation with Cray Research, Inc. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-90-C-1465; ARPA Order 7597)
(AD-A270601; CMU-CS-93-173) Avail: CASI HC A03

In this paper we present a new technique for sparse matrix multiplication on vector multiprocessors based on the efficient implementation of a segmented sum operation. We describe how the segmented sum can be implemented on vector multiprocessors such that it both fully vectorizes within each processor and parallelizes across processors. Because of our method's insensitivity to relative row size, it is better suited than the Ellpack/Itpack or the Jagged Diagonal algorithms for matrices which have a varying number of non-zero elements in each row. Furthermore, our approach requires less preprocessing (no more time than a single sparse matrix-vector multiplication), less auxiliary storage, and uses a more convenient data representation (an augmented form of the standard compressed sparse row format). We have implemented our algorithm (SEGMV) on the Cray Y-MP C90 and have compared its performance with other methods on a variety of sparse matrices from the Harwell-Boeing collection and industrial application codes. Our performance on the test matrices is up to 3 times faster than the Jagged Diagonal algorithm and up to 5 times faster than Ellpack/Itpack method. Our preprocessing time is an order of magnitude faster than for the Jagged Diagonal algorithm. Also, using an assembly language implementation of SEGMV on a 16 processor C90, the NAS Conjugate Gradient benchmark runs at 3.5 gigaflops. DTIC

BOTTOM-UP ABSTRACT INTERPRETATION OF LOGIC PROGRAMS
M. Codish (Katholieke Univ. te Leuven, Belgium.), D. Dams, and E. Yardeni (Weizmann Inst. of Science, Rehovoth, Israel.) 1992 43 p Prepared in cooperation with Katholieke Univ. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191773; COMPUTING SCIENCE NOTES-92/24) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The paper presents a formal framework for the bottom-up abstract interpretation of logic programs which can be applied to approximate answer substitutions, partial answer substitutions, and call patterns for a given program and arbitrary initial goal. The framework is based on T(sub P)-like semantics defined over a Herbrand universe with variables which have previously been shown to determine the answer substitutions for arbitrary initial goals. The first part of the paper reconstructs this semantics to provide a more adequate basis for abstract interpretation. A notion of abstract substitution is introduced and shown to determine an abstract semantic function which for a given program can be applied to approximate the answer substitutions for an arbitrary initial goal. The second part of the paper extends the bottom-up approach to provide approximations of both partial answer substitutions and call patterns. This is achieved by applying Magic Sets and other existing techniques to transform a program in such a way that the answer substitutions of the transformed program correspond to the partial answer substitutions and call patterns of the original program. microfiche quality
(PB93-191823; COMPUTING SCIENCE NOTES-92/15) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

A system that combines polymorphism and higher order functions with logic is presented. The system is suitable for both the functional and the logical paradigms of programming as from the functional paradigms point of view. The system enables one to have all the polymorphism and higher order that exist in functional languages and much more. From the point of view of theorem proving, the system is expressive enough to allow self referential sentences and those sentences that lead to Russell's and Curry's paradoxes. However, the paradoxes do not hold due to the notion of circular types which contain the type of propositions. The system is implemented in Milner's ML and can be seen as extending ML in two important ways. First, it extends the part related to the functional paradigm in that it can type terms that could not be typed in ML; namely, those are the terms that contain self application such as the Y term above. Second, the system extends ML by adding logic to it in a consistent way. NTIS

MULTILIST SCHEDULING: A NEW PARALLEL PROGRAMMING MODEL Ph.D. Thesis
I-Chen Wu 30 Jul. 1993 150 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA972-90-C-0035; ARPA Order 7330)
(AD-A270549; CMU-CS-93-184) Avail: CASI HC A07

Parallel programming requires task scheduling to optimize performance; this primarily involves balancing the load over the processors. In many cases, it is critical to perform task scheduling at runtime. For example, in many parallel applications the task load cannot be accurately predicted a priori, and in a network-based multicomputer, the computational power of each processor may not remain constant. In order to support dynamic task scheduling, the programmer usually needs to design and implement a complex set of scheduling routines, e.g., routines for maintaining task lists and handling interprocessor communication for load balancing. Unfortunately, it is very difficult and time-consuming to write and debug all of these scheduling routines. This thesis proposes a new approach which can greatly reduce the effort of developing efficient dynamic task scheduling routines. In our new approach, we decompose task scheduling into two parts--the specification of scheduling policies and the implementation of supportive scheduling operations--and then hide the latter from the programmer. We call this approach multilist scheduling, because it is based on a uniform scheduling model involving the use of multiple scheduling lists. DTIC

Effective use of large-scale multiprocessors requires the elimination of all bottlenecks that reduce processor utilization. One such bottleneck is memory contention. It is shown that memory contention occurs in many parallel applications, when those applications are run on large-scale shared-memory multiprocessors. In our simulations of several parallel applications on a large-scale machine, it was observed that some applications exhibit near-perfect speedup on hundreds of processors when the effect of memory contention is ignored, and exhibit no speedup at all when memory contention is considered. As the number of processors is increased, many applications exhibit an increase in both the number of hot spots and in the degree of contention for each hot spot. In addition, it was observed that hot spots are spread throughout memory for some applications, and that eliminating hot spots on an individual basis can cause other hot spots to worsen. These observations suggest that modern multiprocessors require some mechanism to alleviate hot-spet contention. The effectiveness of two different mechanisms for dealing with hot-spot contention indirect-connected, distributed-shared-memory multiprocessors is evaluated: queueing requests at the memory module, which allows a memory module to be more highly utilized during period of contention, and increasing the effective bandwidth to memory by having the coherency protocol distribute the hot data to multiple memory modules. It is shown that queueing requires long queues at each memory module, and does not perform as well as our proposed coherency protocol, which essentially eliminates memory contention in the applications considered. Transparent exploitation of parallelism in existing logic programming languages such as PROLOG is focused upon and mature solutions to the problems to be solved in order to obtain efficient implementations are surveyed. These solutions have been implemented and the most efficient parallel logic programming systems reach effective speed-ups over state of the art sequential PROLOG implementations. Current and prospective research issues aiming to extend the applicability and the efficiency of existing systems, such as models merging the transparent parallelism and the concurrent logic languages approaches, combination of constraint logic programming with parallelism, and use of highly parallel architectures, are addressed. FAST DATA PARALLEL POLYGON RENDERING
F. A. Ortega and C. D. Hansen 1993 13 p Presented at the Supercomputing Conference on High Performance Computing and Communications, Portland, OR, 15-19 Nov. 1993
(Contract W-7405-eng-36)
(DE93-040157; LA-UR-93-3173; CONF-931115-11) Avail: CASI HC A03/MF A01

This paper describes a parallel method for polygonal rendering on a massively parallel SIMD machine. This method, based on a simple shading model, is targeted for applications which require very fast polygon rendering for extremely large sets of polygons such as is found in many scientific visualization applications. The algorithms described in this paper are incorporated into a library of 3D graphics routines written for the Connection Machine. The routines are implemented on both the CM-200 and the CM-5. This library enables a scientists to display 3D shaded polygons directly from a parallel machine without the need to transmit huge amounts of data to a post-processing rendering system. DOE

ANALYSIS AND EVALUATION OF CONFIGURING OF GRAPHICAL SYSTEMS ON MULTIPROCESSOR ARCHITECTURES Ph.D. Thesis [ANALYSE UND BEWERTUNG DER KONFIGURIERUNG VON GRAPHISCHEN SYSTEMEN AUF MEHRPROZESSOR-ARCHITEKTUREN]

Martin Goebel 1990 202 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ETN-93-93618) Avail: CASI HC A10

Functional graphical systems for possible parallel processing and the requirements for an implementation on homogeneous multiprocessor systems are examined. Several models, such as standard computer graphics and visualization systems and function and architecture oriented models are considered. A configurating model was developed for data integration, system evaluation, code generation and implementation, installation, and testing. Software tools for configuration, such as data structures, specification interpretation, processor net, and typical structures for sequential, parallel, and pipeline adaptation are described. A multiprocessor prototype, which is available for installation of configurated graphical systems, is presented: a simple software achieves intercommunication and scheduling of current processes. A distributed implementation of the graphical kernel system, which supplies an optimal interprocessor communication between the processor modules, is proposed. ESA

REDUCTION OF NETWORK COST AND WIRING IN RANADE'S BUTTERFLY ROUTING

David Cross (California Univ., Berkeley.), Reinhard Drefenstedt (Saarland Univ., Saarbrucken, Germany.), and Joerg Keller Nov. 1992 9 p Submitted for publication Sponsored in part by DFG Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract NF-62-376)

(CWI-CS-R9243; ETN-94-94723) Copyright Avail: CASI HC A02

The class of n-input butterfly networks is very important for the design of scalable parallel machines because of constant node degree, depth log n and the existence of routing algorithms capable of delivering n log n packets, forming a log n-relation (log n packets destined to each output), in time O(log n) with constant length buffers. Implementations, however, show ugly wiring. A method that, in comparison to the obvious implementation, reduces the number of chips and the number of links between chips in Ranade's butterfly routing by a factor of more than two is presented. The chips remain connected as a butterfly network. This reduction in space simplifies cooling, power supply, and allows for shorter links, thus, reducing wire delay. ESA

MGD1M: A PARALLEL MULTIGRID CODE WITH A FAST VECTORIZED ILU-RELAXATION

Margreet Louter-Nool Nov. 1992 17 p Sponsored by Cray Research, Inc., and Netherlands Organization for Scientific Research Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(CWI-NM-R9222; ETN-93-94697) Copyright Avail: CASI HC A03

MGD1M, a multigrid method which uses incomplete LU relaxation (ILU) as a smoothing process, is addressed. A straightforward ILU implementation leads to non-vectorizable recursive relations. By applying an alternative ordering of the grid points, proposed by Ashcraft et al., the ILU vectorizes and the overall execution time is reduced considerably. General techniques to improve the (vector) performance on the Cray Y-MP4, which are also suitable for other high performance machines, are considered. Parallelism was introduced by applying auto- and macrotasking. Performance results measured on a dedicated Cray Y-MP4/464 are discussed. ESA

OPTIMIZATION OF STATIC TRAFFIC ALLOCATION POLICIES

M. B. Combe and O. J. Boxma Jan. 1993 31 p Sponsored in part by NFI, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant CEC-DG-XIII-BRA-QMIPS)

(CWI-BS-R9302; ETN-94-94719) Copyright Avail: CASI HC A03

The traffic allocation problem is studied: customers in an arrival process have to be assigned to one of a group of servers. Such problems arise in distributed computer systems and flexible manufacturing networks. The aim is to optimize system performance measures, such as mean waiting time of a customer or total number of customers in the system, under a given static allocation policy. Two static policies are considered: probabilistic assignment and allocation according to a fixed pattern. For these two policies, general properties and optimization aspects are discussed. ESA

SCHEDULING FOR LOCALITY IN SHARED-MEMORY MULTIPROCESSORS Technical Report

Evangelos Markatos May 1993 123 p

(Contract N00014-92-J-1801)

(AD-A272948; TR-457) Avail: CASI HC A06/MF A02

The last decade has produced enormous improvements in processor speed without a corresponding improvement in bus or interconnection network speeds. As a result, the relative costs of communication and computation in shared-memory multiprocessors have changed dramatically, and many parallel applications do not execute efficiently on today's multiprocessors. In this dissertation we quantify the effect of this trend-in architecture on parallel program performance, explain the implications of this trend on popular parallel programming models, and propose system software to efficiently map parallel programs and programming models to modern shared-memory multiprocessors. We propose new decomposition and scheduling algorithms that significantly reduce communication overhead. Our experiments over a wide variety of shared-memory multiprocessors demonstrate that the performance benefits of our scheduling-for-locality algorithms are significant, improving performance by up to 60% for some applications. We conclude that communication overhead need not dominate performance, given an appropriate programming model, multiprogramming scheduling policy, and user-level decomposition and scheduling algorithms. OPTIMAL REPAIRMAN ASSIGNMENT IN TWO MAINTENANCE MODELS WHICH ARE EQUIVALENT TO ROUTING MODELS WITH EARLY DECISIONS

Ger Koole Jan. 1993 11 p

(CWI-BS-R9301; ETN-94-94718) Copyright Avail: CASI HC A03/MF A01

Two maintenance models (a warm and a cold standby model) consisting of m parallel groups of identical components are considered. Components have exponentially distributed times to failure. There is a single repairman who can be assigned to the failed components. It is shown for both models that the repairman should be assigned to the group with the

smallest number of functioning components. The maintenance models are equivalent to routing models with delayed state information. The optimality results are obtained by adapting a method which proved to be successful in the study of routing models. ESA

Processors are becoming faster and multiprocessor memory interconnection systems are not keeping up. Therefore, it is necessary to have threads and the memory they access as near one another as possible. Typically, this involves putting memory or caches with the processors, which gives rise to the problem of coherence: if one processor writes an address, any other processor reading that address must see the new value. This coherence can be maintained by the hardware or with software intervention. Systems of both types have been built in the past; the hardware-based systems tended to outperform the software ones. However, the ratio of processor to interconnect speed is now so high that the extra overhead of the software systems may no longer be significant. This issue is explored both by implementing a software maintained system and by introducing and using the technique of offline optimal analysis of memory reference traces. It finds that in properly built systems, software maintained coherence can perform comparably to or even better than hardware maintained coherence. The architectural features necessary for efficient software coherence to be profitable include a small page size, a fast trap mechanism, and the ability to execute instructions while remote memory references are outstanding. The Network Control Center (NCC) Project introduced the concept of total quality management (TQM) in mid-1990. The CSC project team established a program which focused on continuous process improvement in software development methodology and consistent deliveries of high quality software products for the NCC. The vision of the TQM program was to produce error free software. Specific goals were established to allow continuing assessment of the progress toward meeting the overall quality objectives. The total quality environment, now a part of the NCC Project culture, has become the foundation for continuous process improvement and has resulted in the consistent delivery of quality software products over the last three years. Network Control Center (NCC) Project metrics are captured during the implementation and testing phases of the NCCDS software development lifecycle. The metrics data collection and reporting function has interfaces with all elements of the NCC project. Close collaboration with all project elements has resulted in the development of a defined and repeatable set of metrics processes. The resulting data are used to plan and monitor release activities on a weekly basis. The use of graphical outputs facilitates the interpretation of progress and status. The successful application of metrics throughout the NCC project has been instrumental in the delivery of quality software. The use of metrics on the NCC Project supports the needs of the technical and managerial staff. This paper describes the project, the functions supported by metrics, the data that are collected and reported, how the data are used, and the improvements in the quality of deliverable software since the metrics processes and products have been in use. This paper describes a detailed proof-of-concept activity to evaluate flexible scheduling technology as implemented in the Request Oriented Scheduling Engine (ROSE) and applied to Space Network (SN) scheduling. The criteria developed for an operational evaluation of a reusable scheduling system is addressed including a methodology to prove that the proposed system performs at least as well as the current system in function and performance. The improvement of the new technology must be demonstrated and evaluated against the cost of making changes. Finally, there is a need to show significant improvement in SN operational procedures. Successful completion of a proof-of-concept would eventually lead to an operational concept and implementation transition plan, which is outside the scope of this paper. However, a high-fidelity benchmark using actual SN scheduling requests has been designed to test the ROSE scheduling tool. The benchmark evaluation methodology, scheduling data, and preliminary results are described. Author (revised)

USING MANUFACTURING MESSAGE SPECIFICATION FOR MONITOR AND CONTROL AT VENUS c66
W. Randy Heuser, Richard L. Chen, and Michael H. Stockett *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 121-135 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

The flexibility and robustness of a monitor and control (M&C) system are a direct result of the underlying interprocessor communications architecture. A new architecture for M&C at the Deep Space Communications Complexes (DSCC's) has been developed based on the Manufacturing Message Specification (MMS) process control standard of the Open System Interconnection (OSI) suite of protocols. This architecture has been tested both in a laboratory environment and under operational conditions at the Deep Space Network (DSN) experimental Venus station (DSS-13). The Venus experience in the application of OSI standards to support M&C has been extremely successful. MMS meets the functional needs of the station and provides a level of flexibility and responsiveness previously unknown in that environment. The architecture is robust enough to meet current operational needs and flexible enough to provide a migration path for new subsystems. This paper will describe the architecture of the Venus M&C system, discuss how MMS was used and the requirements this imposed on other parts of the system, and provide results from systems and operational testing at the Venus site. PREDICTING SCHEDULING SUCCESS c81
Fredric Messing *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 137-150 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

This paper provides an analytical formulation to predict scheduling success for a class of problems frequently referred to as activity scheduling. Space Network communications scheduling is an example of activity scheduling. The principal assumption is that the activity start times are randomly distributed over the available time in the time line. The formulation makes it possible to estimate how much of the demand can be scheduled as a function of the demand, number of resources, activity duration, and activity flexibility. The paper includes computed results for a variety of resource and demand conditions. The results demonstrate that even with highly flexible activities, it is difficult to schedule demand greater than 60 percent of resources without the use of optimization and conflict resolution capabilities in the scheduling system. DISTRIBUTED INTELLIGENT CONTROL AND STATUS NETWORKING
Andre Fortin and Manoj Patel *In its* Networks Technology Conference Nov. 1993 p 151-161 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

Over the past two years, the Network Control Systems Branch (Code 532) has been investigating control and status networking technologies. These emerging technologies use distributed processing over a network to accomplish a particular custom task. These networks consist of small intelligent 'nodes' that perform simple tasks. Containing simple, inexpensive hardware and software, these nodes can be easily developed and maintained. Once networked, the nodes can perform a complex operation without a central host. This type of system provides an alternative to more complex control and status systems which require a central computer. This paper will provide some background and discuss some applications of this technology. It will also demonstrate the suitability of one particular technology for the Space Network (SN) and discuss the prototyping activities of Code 532 utilizing this technology. Author (revised)

GENERATING AND EVALUATING ALTERNATE SCHEDULES c81
Surender D. Reddy *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 163-180 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

The demand for and availability of Space Network resources are subject to short-term fluctuations and long-term changes. Generation of acceptable schedules under changing demand and resource availability will require the use of different scheduling policies. This paper identifies several such scheduling policies. It defines metrics for evaluating schedules using the criteria directly related to these scheduling policies. Then it applies the metrics to compare several schedules generated for a scenario representative of 1998 SN demand and resources. Finally, the paper describes a method for using these metrics to evaluate schedules based on multiple criteria. Author

THE TEST ANALYSIS RETRIEVAL SYSTEM (TARS): MEETING THE CHALLENGES OF THE NETWORK'S TEST PROCESSES
Robert L. Stelmaszek and Douglas R. Lumsden (Loral AeroSys, Seabrook, MD.) *In its* Networks Technology Conference Nov. 1993 p 181-193 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

The Networks Systems Test Section (GSFC 531.4) is responsible for managing a variety of engineering and operational tests used to assess the status of the Network elements relative to readiness certification for new and ongoing mission support and for performance trending. To conduct analysis of data collected during these tests, to disseminate and share the information, and to catalog and create reports based on the analysis is currently a cumbersome and inefficient task due primarily to the manual handling of paper products and the inability to easily exchange information between the various Networks elements. The Test Analysis and Retrieval System (TARS) is being implemented to promote concise data analysis, intelligible reporting of test results, to minimize test duplication by fostering a broad sharing of test data, and perhaps most importantly, to provide significantly improved response to the Network's internal and external customers. This paper outlines the intended application, architecture, and benefits of the TARS. Author (revised)

ANALYSIS OF THE TDRS MULTIPLE ACCESS SYSTEM FOR POSSIBLE USE AS AN ATTITUDE CONTROL SYSTEM SENSOR c18
Bruce Allyn Blevins and Victor J. Sank (Herold, Fredrick and Associates, Inc., Greenbelt, MD.) *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 195-207 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

A member of the constellation of TDR satellites (TDRS) has experienced a failure of its prime earth sensor. Failure of the remaining earth sensor could result in the inability of the satellite to control its attitude and provide user services. Loss of the satellite would be a serious event. The multiple access (MA) antenna array on the TDRS has been proposed for use as a backup sensor for the attitude control system. This paper describes our analysis of the performance of the MA array as an interferometer used for accurate attitude determination. A least squares fit of a plane to the MA phase information appears to represent the TDRS body roll and pitch within about 0.1 deg. This is sufficient for SGL pointing and MA and SSA user services. Analytic improvements that include ionospheric correction may yield sufficient accuracy for KSA user services. Author (revised)

CASPR is an analysis package which determines the performance of a coded signal in the presence of Radio Frequency Interference (RFI) and Additive White Gaussian Noise (AWGN). It can analyze a system with convolutional coding, Reed-Solomon (RS) coding, or a concatenation of the two. The signals can either be interleaved or non-interleaved. The model measures the system performance in terms of either the E(sub b)/N(sub 0) required to achieve a given Bit Error Rate (BER) or the BER needed for a constant E(sub b)/N(sub 0). AN IN-DEPTH ANALYSIS AND MODELLING OF THE SHUTTLE TO MILA S-BAND TELEMETRY LINK c17
Armen Caroglanian, Fernando A. Pellerano, and Dale D. Shama (Loral AeroSys, Seabrook, MD.) *In its* Networks Technology Conference Nov. 1993 p 217-224 (For primary document see N94-21323 05-62)
Avail: CASI HC A02/MF A03

The S-Band radio frequency (RF) link between the Merritt Island (MILA) Tracking Station and the Space Shuttle launch pads is a critical communication path for prelaunch and launch operations. The proposed siting of the Center for Space Education (CSE) at the Visitor Center required a study to avoid RF line-of-sight blockage and reflection paths. The study revealed the trees near MILA's 9-meter (9-M) antennas are obstructing the optical line-of-sight. The studies found diffraction is the main propagation mechanism. This paper describes a link model based on the Geometric Theory of Diffraction. Author

THE AUTOMATED CONFLICT RESOLUTION SYSTEM (ACRS) c32
Ted Kaplan, Andrew Musliner, and David Wampler *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 225-233 (For primary document see N94-21323 05-62)
Avail: CASI HC A02/MF A03

The Automated Conflict Resolution System (ACRS) is a mission-current scheduling aid that predicts periods of mutual interference when two or more orbiting spacecraft are scheduled to communicate with the same Tracking and Data Relay Satellite (TDRS) at the same time. The mutual interference predicted has the potential to degrade or prevent communications. Thus the ACRS system is a useful tool for aiding in the scheduling of Space Network (SN) communications. DEVELOPING A SPACE NETWORK INTERFACE SIMULATOR: THE NTS APPROACH c66
Gary E. Hendrzak *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 243-251 (For primary document see N94-21323 05-62)
Avail: CASI HC A02/MF A03

This paper describes the approach used to redevelop the Network Control Center (NCC) Test System (NTS), a hardware and software facility designed to make testing of the NCC Data System (NCCDS) software efficient, effective, and as rigorous as possible prior to operational use. The NTS transmits and receives network message traffic in real-time. Data transfer rates and message content are strictly controlled and are identical to that of the operational systems. NTS minimizes the need for costly and time-consuming testing with the actual external entities (e.g., the Hubble Space Telescope (HST) Payload Operations Control Center (POCC) and

the White Sands Ground Terminal). Discussed are activities associated with the development of the NTS, lessons learned throughout the project's lifecycle, and resulting productivity and quality increases. Author (revised)

SATELLITE COMMUNICATION HARDWARE EMULATION SYSTEM (SCHES) **c32**
Ted Kaplan *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 253-263 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

Satellite Communication Hardware Emulator System (SCHES) is a powerful simulator that emulates the hardware used in TDRSS links. SCHES is a true bit-by-bit simulator that models communications hardware accurately enough to be used as a verification mechanism for actual hardware tests on user spacecraft. As a credit to its modular design, SCHES is easily configurable to model any user satellite communication link, though some development may be required to tailor existing software to user specific hardware. Avail: CASI HC A02/MF A03

This paper describes the packet switched Instrumenters Communication System (ICS) that was developed for the Command Management Facility at GSFC to support the Gamma Ray Observatory (GRO) spacecraft. The GRO ICS serves as a vital science data acquisition link to the GRO scientists to initiate commands for their spacecraft instruments. The system is ready to send and receive messages at any time, 24 hours a day and seven days a week. The system is based on X.25 and the International Standard Organization's (ISO) 7-layer Open Systems Interconnection (OSI) protocol model and has client and server components. The components of the GRO ICS are discussed along with how the Communications Subsystem for Interconnection (CSFI) and Network Control Program Packet Switching Interface (NPSI) software are used in the system. USING THE USCCS FOR SUB MICROSECOND SPACECRAFT CLOCK CALIBRATION **c35**
Victor J. Sank *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 275-287 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

The Return Data Delay technique which requires knowledge of spacecraft range is commonly used for correlating a spacecraft clock against a ground time standard when millisecond accuracy is required. An analysis is presented that allows using the user spacecraft clock calibration system (USCCS) to correlate a spacecraft clock to better than one microsecond accuracy. The basic USCCS algorithm has been simplified and it is shown to result in about one microsecond accuracy without requiring orbital information. By considering the relative motion of the user satellite, the TDRS and the earth station about the center of the earth, a correction of almost two orders of magnitude can be made. Such accuracy is required for scientific investigations that require correlating coincident radiation or particle detection with a remote laboratory. Author (revised)

ARRAY SIMULATIONS PLATFORM (ASP) PREDICTS NASA DATA LINK MODULE (NDLM) PERFORMANCE **c32**
Allen David Snook *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 309-327 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

Through a variety of imbedded theoretical and actual antenna patterns, the array simulation platform (ASP) enhanced analysis of the array antenna pattern effects for the KTx (Ku-Band Transmit) service of the NDLM (NASA Data Link Module). The ASP utilizes internally stored models of the NDLM antennas and can develop the overall pattern of antenna arrays through common array calculation techniques. ASP expertly assisted in the diagnosing of element phase shifter errors during KTx testing and was able to accurately predict the overall array pattern from combinations of the four internally held element patterns. This paper provides an overview of the use of the ASP software in the solving of array mis-phasing problems. Author (revised)

CONVERSION OF THE PROPRIETARY ROLM (TM) INTER-NODE LINK FROM MULTIMODE TO SINGLEMODE OPERATION **c32**
Larry Boucher *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 329-347 (For primary document see N94-21323 05-62)
Avail: CASI HC A03/MF A03

Many NASA centers have selected ROLM(TM) Computerized Branch Exchanges (CBX's) as their standard telephone exchange. The ROLM 9751 CBX Model 70 with ROLM software release 9005 can inter-communicate as a 'multi-node' system over a multimode fiber optic link of 450 to 6,000 meters. Singlemode fiber installations are not supported by ROLM. Two New Mexico-based NASA satellite ground terminals were already connected via a 6 kilometer singlemode fiber optic link. The ROLM Inter-Node Link (INL) was converted from multimode LED transmitters to singlemode laser transmitters and two ROLM CBX systems were interconnected using the modified INL. On activation, the system operated normally and has done so for six months. System testing indicates sufficient margin to drive 45 kilometers of singlemode fiber, an important benefit for widely separated facilities. Author (revised)

ADVANCED CODING AND MODULATION SCHEMES FOR TDRSS **c32**
Linda Harrell, Ted Kaplan, Ted Berman, and Susan Chang *In* NASA. Goddard Space Flight Center, Networks Technology Conference Nov. 1993 p 349-354 (For primary document see N94-21323 05-62)
Avail: CASI HC A02/MF A03

This paper describes the performance of the Ungerboeck and pragmatic 8-Phase Shift Key (PSK) Trellis Code Modulation (TCM) coding techniques with and without a (255,223) Reed-Solomon outer code as they are used for Tracking Data and Relay Satellite System (TDRSS) S-Band and Ku-Band return services. The performance of these codes at high data rates is compared to uncoded Quadrature PSK (QPSK) and rate 1/2 convolutionally coded QPSK in the presence of Radio Frequency Interference (RFI), self-interference, and hardware distortions. This paper shows that the outer Reed-Solomon code is necessary to achieve a 10(exp -5) Bit Error Rate (BER) with an acceptable level of degradation in the presence of RFI. This paper also shows that the TCM codes with or without the Reed-Solomon outer code do not perform well in the presence of self-interference. In fact, the uncoded QPSK signal performs better than the TCM coded signal in the self-interference situation considered in this analysis. Finally, this paper shows that the E(sub b)/N(sub 0) degradation due to TDRSS hardware distortions is approximately 1.3 dB with a TCM coded signal or a rate 1/2

convolutionally coded QPSK signal and is 3.2 dB with an uncoded QPSK signal. Author (revised)

Avail: CASI HC A03/MF A03

The Network Command Processing System (NCPS) developed for the National Aeronautics and Space Administration (NASA) Ground Network (GN) stations is a spacecraft command system utilizing a MULTIBUS I/68030 microprocessor. This system was developed and implemented at ground stations worldwide to provide a Project Operations Control Center (POCC) with command capability for support of spacecraft operations such as the LANDSAT, Shuttle, Tracking and Data Relay Satellite, and Nimbus-7. The NCPS consolidates multiple modulation schemes for supporting various manned/unmanned orbital platforms. The NCPS interacts with the POCC and a local operator to process configuration requests, generate modulated uplink sequences, and inform users of the ground command link status. This paper presents the system functional description, hardware description, and the software design. Author (revised)

A distributed system is self stabilizing if it can be started in any possible global state. Once started the system regains its consistency by itself, without any kind of an outside intervention. The self stabilization property makes the system tolerant to faults in which processors crash and then recover spontaneously in an arbitrary state. When the intermediate period in between one recovery and the next crash is long enough the system stabilizes. A distributed system is uniform if all processors with the same number of neighbors are identical. A study on uniform self stabilizing protocols for leader election under read/write atomicity is presented. The protocols use randomization to break symmetry. The si-game method for analyzing the performance of randomized distributed protocols is introduced and two protocols for the case where each processor in the system can communicate with all other processors are presented. Their performance is analyzed using the si-game technique. ESA

(Contract W-7405-eng-36)
(DE93-040150; LA-UR-93-3138; CONF-9310153-1) Avail: CASI HC A03/MF A01

This paper presents a divide-and-conquer ray-traced volume rendering algorithm and its implementation on networked workstations and a massively parallel computer, the Connection Machine CM-5. This algorithm distributes the data and the computational load to individual processing units to achieve fast, high-quality rendering of high-resolution data, even when only a modest amount of memory is available on each machine. The volume data, once distributed, is left intact. The processing nodes perform local ray-tracing of their sub-volume concurrently. No communication between processing units is needed during this locally ray-tracing process. A sub-image is generated by each processing unit and the final image is obtained by compositing sub-images in the proper order, which can be determined a priori. Implementations and tests on a group of networked workstations and on the Thinking Machines CM-5 demonstrate the practicality of our algorithm and expose different performance tuning issues for each platform. We use data sets from medical imaging and computational fluid dynamics simulations in the study of this algorithm. DOE

SIMULATED BEHAVIOUR OF LARGE SCALE SCI RINGS AND TORI
Ho-Jung Cha (Manchester Univ., England.), A. Knowles (Manchester Univ., England.), and R. Daniel, Jr. (Cambridge Univ., England.) 1993 10 p Presented at the 5th Institute of Electrical and Electronics Engineers (IEEE) Symposium on Parallel and Distributed Processing, Dallas, TX, 1-4 Dec. 1993
(Contract W-7405-eng-36)
(DE93-040149; LA-UR-93-3137; CONF-931220-2) Avail: CASI HC A02/MF A01

SCI (Scalable Coherent Interface) is a new IEEE standard for a high speed interconnect in parallel processors. It is attracting interest because of its high bandwidth (1 GB/sec/link) and low latency. The default SCI topology is a ring, which does not scale well to large numbers of processors. This paper uses stochastic and trace-driven simulations to compare the performance of SCI-based parallel computers with a ring topology to those based on a torus topology. We also look at the effects of varying some of the internals of the SCI components. DOE

PERFORMANCE EVALUATION OF VIDEO ON ETHERNET
M. Pihlman and R. Farrell Aug. 1993 8 p
(Contract W-7405-eng-48)
(DE93-040696; UCRL-ID-115116) Avail: CASI HC A02/MF A01

The purpose of this project was to determine the feasibility of using an ethernet local area network (LAN) to support videoconferencing connections between CAMEO Macintosh desktop videoconferencing systems. The specific goals were to: (1) to ensure that CAMEO video could be transported-without protocol modification-via existing ethernet networks, and would do so without "bringing-down" the network; (2) to measure the effect of CAMEO video connections on ethernet traffic; (3) to evaluate qualitatively how generated ethernet traffic effects the CAMEO video; and (4) to evaluate qualitatively how multiple CAMEO connections work between two routered ethernet networks via a backbone. High quality CAMEO video can be transported on an ethernet network and between routered networks, via a backbone. The number of simultaneous video connections possible on an ethernet segment would probably be less than 45, since each connection uses 2.2% of the network and errors increase rapidly as video connections are made. However, the actual number of simultaneous video connections possible will depend upon your network implementation and the amount of 'normal' traffic present. The remainder of this report discusses the effect of CAMEO video on our networks. DOE

In contemplating the transition from sequential to MP computing, the National Energy Research Supercomputer Center (NERSC) is faced with the frictions inherent in the duality of its mission. There have been two goals: the first has been to provide a stable, serviceable, production environment to the user base; the second to bring the most capable early serial supercomputers to the center to make possible the leading edge simulations. This seeming conundrum has in reality been a source of strength. The task of meeting both goals was faced before with the CRAY 1 which, as delivered, was all iron; so the problems associated with the advent of parallel computers are not entirely new, but they are serious. Current vector supercomputers, such as the C90, offer mature production environments, including software tools, a large applications base, and generality; these machines can be used to attack the spectrum of scientific applications by a large user base knowledgeable in programming techniques for this architecture. Parallel computers to date have offered less developed, even rudimentary, working environments, a sparse applications base, and forced specialization. They have been specialized in terms of programming models, and specialized in terms of the kinds of applications which would do well on the machines. Given this context, why do many service computer centers feel that now is the time to cease or slow the procurement of traditional vector supercomputers in favor of MP systems? What are some of the issues that NERSC must face to engineer a smooth transition? The answers to these questions are multifaceted and by no means completely clear. However, a route exists as a result of early efforts at the laboratories combined with research within the HPCC program. One can begin with an analysis of why the hardware and software appearing shortly should be made available to the mainstream, and then address what would be required in an initial production environment. DOE

EVALUATION OF DEC'S GIGAswitch FOR DISTRIBUTED PARALLEL COMPUTING
H. Chen, J. Hutchins, and J. Brandt Oct. 1993 30 p
(Contract DE-AC04-76DR-00789)
(DE94-001356; SAND-93-8013) Avail: CASI HC A03/MF A01

One of Sandia's research efforts is to reduce the end-to-end communication delay in a parallel-distributed computing environment. GIGAswitch is DEC's implementation of a gigabit local area network based on switched FDDI technology. Using the GIGAswitch, the authors intend to minimize the medium access latency suffered by shared-medium FDDI technology. Experimental results show that the GIGAswitch adds 16.5 microseconds of switching and bridging delay to an end-to-end communication. Although the added latency causes a 1.8% throughput degradation and a 5% line efficiency degradation, the availability of dedicated bandwidth is much more than what is available to a workstation on a shared medium. For example, ten directly connected workstations each would have a dedicated bandwidth of 95 Mbps, but if they were sharing the FDDI bandwidth, each would have 10% of the total bandwidth, i.e., less than 10 Mbps. In addition, they have found that when there is no output port contention, the switch's aggregate bandwidth will scale up to multiples of its port bandwidth. However, with output port contention, the throughput and latency performance suffered significantly. Their mathematical and simulation models indicate that the GIGAswitch line efficiency could be as low as 63% when there are nine input ports contending for the same output port. The data indicate that the delay introduced by contention at the server workstation is 50 times that introduced by the GIGAswitch. The authors conclude that the GIGAswitch meets the performance requirements of today's high-end workstations and that the switched FDDI technology provides an alternative that utilizes existing workstation interfaces while increasing the aggregate bandwidth. However, because the speed of workstations is increasing by a factor of 2 every 1.5 years, the switched FDDI technology is only good as an interim solution. DOE

The current systems architecture for the SSCL's Physics Detector Simulation Facility (PDSF) is presented. Systems analysis data is presented and discussed. In particular, these data disclose the effectiveness of utilization of the facility for meeting the needs of physics computing, especially as concerns parallel architecture and processing. Detailed design plans for the highly networked, symmetric, parallel, UNIX workstation-based facility are given and discussed in light of the design philosophy. Included are network, CPU, disk, router, concentrator, tape, user and job capacities and throughput. DOE

(DE93-018791; PNL-SA-22001; CONF-9303204-1) Avail: CASI HC A02/MF A01

Several algorithms are discussed for implementing global combine on distributed memory computers using a two-dimensional mesh interconnect with wormhole routing. These include algorithms that are asymptotically optimal for short vectors (O(log(p)) for p processors) and for long vectors (O(n) for n data elements per processor). Performance models are developed which include startup and transfer costs that can depend on the number of messages that each node must handle at once. The models are validated using experimental data from the Intel Touchstone DELTA computer.

Atomistic Molecular Dynamics and Lagrangian Continuum Mechanics can be very similarly adapted to massively-parallel computers. Millions of degrees of freedom can be treated. The two complementary approaches, microscopic and macroscopic, are being applied to increasingly realistic flows of fluids and solids. The two approaches can also be combined in a hybrid simulation scheme. Hybrids combine the fundamental constitutive advantage of atoms with the size advantage of the continuum picture.

DISTRIBUTED PROCESSING USING ORACLE7 AND SQL*NET V2: AN IMPLEMENTATION STORY

J. P. Loftis and J. W. Grubb (Tennessee Univ., Knoxville.) 1993 9 p Presented at the 1993 International Oracle Users' Meeting, Orlando, FL, 26 Sep. - 1 Oct. 1993

(Contract DE-AC05-84OR-21400)

(DE94-000494; CONF-9309246-1) Avail: CASI HC A02/MF A01

The Army is successfully building on the Oracle7 system that includes a central data repository and decentralized processing hubs. One of the greatest challenges of this project is to connect multiple sites on the East, West, and Gulf Coasts with a database server and to distribute large volumes of data and messages between this database and Orcale7 nodes using SQL*Net. This presentation describes the problems we encountered, the solutions we found, and our success using Orcale7 and SQL*Net to provide global visibility of shipment cargo.

DISTRIBUTED INPUT/OUTPUT PROCESSING IN DATA-DRIVEN MULTIPROCESSORS

P. Evripidou (Southern Methodist Univ., Dallas, TX.) and J. L. Gaudiot 1992 9 p Presented at the 2nd IEEE Symposium on Parallel and Distributed Processing, Dallas, TX, 9-13 Dec. 1990

(Contract DE-FG03-87ER-25043)

(DE94-000323; CONF-901221-2) Avail: CASI HC A02/MF A01

Data-flow principles of execution provide an elegant way to ensure at runtime that instructions can be executed asynchronously in a parallel environment. However, while the conventional von Neumann model of interpretation has a very rigid ordering of instructions, it is the very asynchronous character of the dataflow model of execution that introduces conflicts when 'state' tasks (such as I/O operations) must share common data objects. In order to execute I/O operations safely and in parallel, an algorithm to detect and classify cases of potential conflicts (hazards) has been developed; it is described in this paper. It is based upon localizing the effect of I/O operations by splitting the data-flow graph into two subgraphs: (1) the computation subgraph, and (2) the I/O subgraph. The scheme presented in this paper thus enables the creation and interaction of both subgraphs, which in turn yields a deterministic execution. Furthermore, the proposed scheme enables the distributed execution of I/O operations as permitted by data dependencies.

This technical report contains the Higher-Order Logic (HOL) listings of the partial verification of the requirements and design for a commercially developed processor interface unit (PIU). The PIU is an interface chip performing memory interface, bus interface, and additional support services for a commercial microprocessor within a fault tolerant computer system. This system, the Fault Tolerant Embedded Processor (FTEP), is targeted towards applications in avionics and space requiring extremely high levels of mission reliability, extended maintenance-free operation, or both. This report contains the actual HOL listings of the PIU verification as it currently exists. Section two of this report contains general-purpose HOL theories and definitions that support the PIU verification. These include arithmetic theories dealing with inequalities and associativity, and a collection of tactics used in the PIU proofs. Section three contains the HOL listings for the completed PIU design verification. Section 4 contains the HOL listings for the partial requirements verification of the P-Port. Derived from text

PARALLEL FUNCTIONAL PROGRAMMING IN SISAL: FICTIONS, FACTS, AND FUTURE

J. R. McGraw 1 Jul. 1993 40 p Presented at the Programming Tools for Parallel Machines Workshop, Otranto, Italy, 22-26 Jun. 1993

(Contract W-7405-eng-48)

(DE93-040486; UCRL-JC-114360; CONF-9306250-1) Avail: CASI HC A03/MF A01

This paper provides a status report on the progress of research and development on the functional language Sisal. This project focuses on providing a highly effective method of writing large scientific applications that can efficiently execute on a spectrum of different multiprocessors. The paper includes sections on the language definition, compilation strategies, and programming techniques intended for readers with little or no background with Sisal. The section on performance presents our most recent results on execution speed for shared-memory multiprocessors, our findings using Sisal to develop codes, and our experiences migrating the same source code to different machines. For large programs, the execution performance of Sisal (with minimal supporting advice from the programmer) usually exceeds that of the best available automatic, vector/parallel Fortran compilers. Our evidence also indicates that Sisal programs tend to be shorter in length, faster to write, and clearer to understand than equivalent algorithms in Fortran. The paper concludes with a substantial discussion of common criticisms of the language and our plans for addressing them. Most notably, efficient implementations for distributed memory machines are lacking; an issue we plan to remedy.

In this paper we describe a self-adjusting algorithm for packet routing, in which a reinforcement learning module is embedded into each node of a switching network. Only local communication is used to keep accurate statistics at each node on which routing policies lead to minimal delivery times. In simple experiments involving a 36-node, irregularly connected network, this learning approach proves superior to a nonadaptive algorithm based on precomputed shortest paths. DTIC

We describe a project to capitalize on newly available levels of computational resources in order to understand human cognition. We will build an integrated physical system including vision, sound input and output, and dextrous manipulation, all controlled by a continuously operating large scale parallel MIMD computer. The resulting system will learn to 'think' by building on its bodily experiences to accomplish progressively more abstract tasks. Past experience suggests that in attempting to build such an integrated system we will have to fundamentally change the way artificial intelligence, cognitive science, linguistics, and philosophy think about the organization of intelligence. We expect to be able to better reconcile the theories that will be developed with current work in neuroscience. DTIC

WHY STEREO VISION IS NOT ALWAYS ABOUT 3D RECONSTRUCTION Memorandum Report

W. E. Grimson Jul. 1993 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-91-J-4038; NSF IRI-89-00267)

(AD-A270522; AIM-1435) Avail: CASI HC A03

A common assumption of stereo vision researchers is that the goal of stereo is to compute explicit 3D information about a scene, to support activities such as navigation, hand-eye coordination and object recognition. This paper suggests reconsidering what is required of a stereo algorithm, in light of the needs of the task that uses its output. We show that very accurate camera calibration is needed to reconstruct accurate 3D distances, and argue that often it may be difficult to attain and maintain such accuracy. We further argue that for tasks such as object recognition, separating object from background is of central importance. We suggest that stereo can help with this task, without explicitly computing 3D information. We provide a demonstration of a stereo algorithm that supports separating figure from ground through attentive fixation on key features. DTIC

LARGE DEVIATIONS BEHAVIOR OF COUNTING PROCESSES AND THEIR INVERSES

Peter W. Glynn and Ward Whitt Jul. 1993 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DAAL03-91-G-0101)

(AD-A271142; SU-TR-93-7; ARO-28809.14-MA-SDI) Avail: CASI HC A03

We show, under regularity conditions, that a counting process satisfies a large deviations principle in R, a sample-path large deviations principle in the function space D, or the Gartner-Ellis condition (convergence of the normalized logarithmic moment generating functions), if and only if, its inverse process does. We show, again under regularity conditions, that an embedded regenerative structure is sufficient for the counting process or its inverse process to have exponential asymptotics and thus satisfy the Gartner-Ellis condition. These results help characterize the small-tail asymptotic behavior of steady-state distributions in queueing models, e.g., the waiting time, workload, and queue length. DTIC

AN EXPERT SYSTEM EXECUTIVE FOR AUTOMATED ASSEMBLY OF LARGE SPACE TRUSS STRUCTURES

Cheryl L. Allen Nov. 1993 20 p Sponsored by NASA. Washington (RTOP 586-02-11)

(NASA-TM-4487; L-17189; NAS 1.15:4487) Avail: CASI HC A03/MF A01

Langley Research Center developed a unique test bed for investigating the practical problems associated with the assembly of large space truss structures using robotic manipulators. The test bed is the result of an interdisciplinary effort that encompasses the full spectrum of assembly problems - from the design of mechanisms to the development of software. The automated structures assembly test bed and its operation are described, the expert system executive and its development are detailed, and the planned system evolution is discussed. Emphasis is on the expert system implementation of the program executive. The executive program must direct and reliably perform complex assembly tasks with the flexibility to recover from realistic system errors. The employment of an expert system permits information that pertains to the operation of the system to be encapsulated concisely within a knowledge base. This consolidation substantially reduced code, increased flexibility, eased software upgrades, and realized a savings in software maintenance costs. Author

APPLICATION OF CHANGE DETECTION TO DYNAMIC CONTACT SENSING Memorandum Report

Brian Eberman and J. K. Salisbury, Jr. Mar. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contracts N00014-91-J-4038; N00014-92-J-1814)

(AD-A270523; AIM-1421) Avail: CASI HC A03

The forces of contact during manipulation convey substantial information about the state of the manipulation. Textures, slip, impacts, grasping, and other contact conditions produce force and position signatures that can be used for identifying the state of contact. This paper addresses the fundamental problems of interpreting the force signals without any additional context on the state of manipulation. Techniques based on forms of the generalized sequential likelihood ratio test are used to segment individual strain signals into statistically equivalent pieces. The results of the segmentation are designed to be used in a higher level procedure which will interpret the results within a manipulation context. We report on our experimental development of the segmentation algorithm and on its results for detecting and labelling impacts, slip, changes in texture, and condition. The sequential likelihood ratio test is reviewed and some of its special cases and optimal properties are discussed. Finally, we conclude by discussing extensions to the techniques and lessons for sensor design. DTIC

ROBOT SKILL LEARNING AND THE EFFECTS OF BASIS FUNCTION CHOICE

J. G. Schneider and C. M. Brown Sep. 1992 45 p

(Contract NSF IRI-89-20771; NSF CDA-88-22724; MDA972-92-J-1012)

(TR-437) Avail: CASI HC A03/MF A01

We present a computational, constructive theory of tunable, open loop trajectory skills. A skill is a controller whose outputs achieve any task in a space characterized by n parameters, n greater than 1. Throwing a ball at a target is a 3-dimensional task if the target may be anywhere within a 3-dimensional volume. Repetitious pick and place tasks are zero-dimensional, and thus not skills. Skills are performed open loop for speed reasons: we assume the entire command sequence is generated before any feedback can become available. We do not assume prior knowledge of plant or task models, so skills must be at least partly learned. A skill output is a vector of values -- in our work so far it is generated as the sum of a base vector and a weighted change vector whose weight accomplishes the tuning. Learning consists of a search for the best set of base and change vectors. An interpretation process maps skill outputs into sequences of commands for the plant by using basis functions (given a priori in this paper). The basis functions may be arbitrarily complex. We claim that appropriate basis functions can speed up the learning process and overcome the limitations of the linear trajectory tuning algorithm. This report describes a skill learning algorithm and experiments done with various basis functions and control methods for a one-dimensional throwing task. It concludes with a discussion of future work in learning basis functions, higher dimensional tasks, and comparisons against common learning and control algorithms. Author

SELF-ORGANIZATION VIA ACTIVE EXPLORATION IN ROBOTIC APPLICATIONS. PHASE 2: HYBRID HARDWARE PROTOTYPE Final Progress Report

Haluk Oegmen Dec. 1993 51 p Sponsored by NASA. Lyndon B. Johnson Space Center

(NASA-CR-194723; NAS 1.26:194723) Avail: CASI HC A04/MF A01

In many environments human-like intelligent behavior is required from robots to assist and/or replace human operators. The purpose of these robots is to reduce human time and effort in various tasks. Thus the robot should be robust and as autonomous as possible in order to eliminate or to keep to a strict minimum its maintenance and external control. Such requirements lead to the following properties: fault tolerance, self organization, and intelligence. A good insight into implementing these properties in a robot can be gained by considering human behavior. In the first phase of this project, a neural network architecture was developed that captures some fundamental aspects of human categorization, habit, novelty, and reinforcement behavior. The model, called FRONTAL, is a 'cognitive unit' regulating the exploratory behavior of the robot. In the second phase of the project, FRONTAL was interfaced with an off-the-shelf robotic arm and a real-time vision system. The components of this robotic system, a review of FRONTAL, and simulation studies are presented in this report. Derived from text

An algorithm for a two dimensional representation of the acoustic signal of spoken words is presented. Having such an algorithm, the result for different applications like speech recognition and machine control by voice can be used. If such a map from the domain of continuous speech signals to a two (or three) dimensional Euclidean space can be argued to be a reasonable model of the human speech processing system, then psycholinguistic phenomena can even be investigated with this model. The algorithm is in fact a shortcut for a self organizing artificial neural network as developed by Kohonen. ESA

Recent efforts to model the remarkable ability of humans to recognize speech and words are described. Different techniques including the use of neural nets for representing phonological similarity between words in the lexicon with self organizing algorithms are discussed. Simulations using the standard Kohonen algorithm are presented to illustrate some problems confronted with this technique in modeling similarity relations of form in the human mental lexicon. Alternative approaches that can potentially deal with some of these limitations are sketched. ESA

The application of neural nets to speech synthesis is considered. In speech synthesis, the main efforts so far have been to master the grapheme to phoneme conversion. During this conversion symbols (graphemes) are converted into other symbols (phonemes). Neural networks, however, are especially competitive for tasks in which complex nonlinear transformations are needed and sufficient domain specific knowledge is not available. The conversion of text into speech parameters appropriate as input for a speech generator seems such a task. Results of a pilot study in which an attempt is made to train a neural network for this conversion are presented. ESA

GENERALIZATION PERFORMANCE OF BACKPROPAGATION LEARNING ON A SYLLABIFICATION TASK

Walter Daelemans and Antal vandenBosch *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 27-37 (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A03/MF A02

The generalization capabilities of backpropagation learning in feedforward and recurrent feedforward connectionist networks on the assignment of syllable boundaries to orthographic representations in Dutch (hyphenation) was investigated. This is a difficult task because phonological and morphological constraints interact, leading to ambiguity in the input patterns. The results are compared to different symbolic pattern matching approaches, and to an exemplar based generalization scheme, related to a k-nearest neighbor approach, but using a similarity metric weighed by the relative information entropy of positions in the training patterns. The results indicate that the generalization performance of backpropagation learning for this task is not better than that of the best symbolic pattern matching approaches, and of examplar based generalization. REPRESENTATION OF IDIOMS IN CONNECTIONIST MODELS

Erik-Jan vanderLinden and Wessel Kraaij *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 39-46 (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A02/MF A02

The resolution of the ambiguity between the nonidiomatic and the idiomatic reading of a phrase that is possibly idiomatic is discussed. A choice between these readings can be made using various kinds of linguistic information, but it is claimed that it can be made on the basis of the mere fact that one of the analyses is idiomatic, and that this choice does not have to be stipulated explicitly, but follows naturally from the architecture of the lexicon and the retrieval process, if an appropriate model of the lexicon is used. It is argued that a connectionist model is appropriate, and some comparisons with symbolic models are made, especially with hierarchical models of the lexicon. ESA

NEURAL DATA ORIENTED PARSING

Jan C. Scholtes *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 47-52 Sponsored by MSC Beheer BV, Netherlands (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A02/MF A02

Results of a hybrid parsing model that combines the speed of statistical and corpus based parsing methods with the disambiguation power of traditional production-rule systems are presented. Parsing consists of deriving the most probable structure (from fragments) that already exist in the corpus. The Data Oriented Parsing (DOP) paradigm uses statistical features of language in combination with a structured corpus. The derivation of the 'probabilities' and the storage of the corpus is done by means of a Kohonen feature map. The actual data oriented parsing is performed by a regular Von Neumann machine. The model can process incomplete sentences, wrong sentences and completely new sentences which contain a certain number of unknown words or structures. Implicit features of the Kohonen model turn the ranking of possible parses and the selection of the most probable one into a straightforward task. ESA

Connectionist techniques are useful for modeling sentence comprehension because they allow competition between information of different sources to achieve a result. Present connectionist models of sentence comprehension are capable of assigning thematic roles to constituents which consist of simple lexical elements. A method which makes possible assignment of roles to constituents which consist of larger stuctures is described. ESA

HOPFIELD MODELS AS NEURAL-NETWORK ACCEPTORS

Marc F. J. Drossaers *In its* Connectionism and Natural Language Processing Oct. 1992 p 57-65 (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A02/MF A02

The first results of research into the use of neural networks for integrated linguistic analysis, a Hopfield model for syntactical analysis, are presented. A neural network is constructed as an implementation of a bounded push down automaton, which can accept context free languages with limited center embedding. The network's behavior can be predicted a priori, so the presented theory can be tested. The operation of the network as an implementation of the acceptor is probably correct. Furthermore a solution to the problem of spurious states in Hopfield models was found: they are used as dynamically constructed representations of sets of states of the implemented acceptor. The so called neural network acceptor proposed, is fast but large. ESA

A SINGLE LAYER HIGHER ORDER NEURAL NET AND ITS APPLICATION TO GRAMMAR RECOGNITION

Peter Wyard *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 67-85 (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A03/MF A02

A single layer Higher Order Dynamic Topology Neural Net (HODYNE) is described, targeted at natural language processing problems. HODYNE has an input layer of nodes containing concatenations of words from the input string, and grows nodes during training which are dependent on the training data. The training procedure also has some novel features. Results are presented on the problem of grammaticality determination. The results are encouraging, with almost perfect performance on unseen test sets derived from simple context free grammars, and promising performance of sentences taken from the LOB Corpus of British English. On the latter task, the performance of HODYNE is compared with that of a method based on the statistics of tag-pairs and with a multilayer perceptron. ESA

A MODULAR DESIGN FOR CONNECTIONIST PARSING

Noel E. Sharkey and Amanda J. C. Sharkey *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 87-96 Sponsored by British Telecom (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A02/MF A02

Research on network combination for natural language processing is reported. A modular parser is reported that utilizes three different connectionist architectures: a simple recurrent net, a feedforward net, and a recursive auto associative net. Each of these was trained individually on specialist tasks and then components of the architectures were linked to form an integrated system. The combination parser accepts sentences that are input sequentially, a word at a time, and produces a syntactic tree as output. As well as parsing the 1280 sentences for which the components had been trained, it correctly disambiguated 75.62% of a set of 320 novel structurally ambiguous sentences. This is impressive given that the system developed its own lexical rules and had no access to semantic or pragmatic information other than that implicit in the training sets. The results are discussed in terms of modular principles and the types of rules that the unified parser extracts from its modules. The kinds of operations that can be performed on compressed holistic connectionist representations are illustrated. ESA

AN EXPLORATION OF CLAUSE BOUNDARY EFFECTS IN SRN REPRESENTATIONS **c62**

Ronan Reilly *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 97-102 (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A02/MF A02

A study carried out on the psychological plausibility of the language representations developed by Elman style Simple Recurrent Networks (SRN's) is described. These representations were discussed at length in Elman (1991) from the perspective of their capacity to represent complex structural relationships, and their ability to accommodate the open endedness of language within a fixed resource system. Although there is some suggestion that SRN representations have properties that make them psychologically plausible, this has not been put to a direct test. It is shown how two well known clause boundary memory effects are a consequence of the nature of SRN representations rather than an interaction with an external memory mechanism. ESA

SYNTACTIC NEURAL NETWORKS FOR NATURAL LANGUAGE PROCESSING

S. M. Lucas *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 103-114 (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A03/MF A02

An introduction to Syntactic Neural Networks (SNN) is given and the algebraic grammatical inference algorithm is presented. An SNN is a special modular neural architecture derived from the matrix method of parsing context free grammars. The special structure of the network gives it a head start over other types of neural architecture when dealing with problems requiring grammar based solutions, since general knowledge about how to parse is embedded in the network architecture, and need not be learned afresh for each new problem. An SNN comes preequipped to deal with grammars, it need only learn the details of the grammar from the training set, which is still very difficult. The algebraic inferencing method forms algebraic expressions for the net output for each input string, and performs constraint satisfaction to try and find an assignment to the variables (and hence a grammar) that will parse all the positive strings and none of the negative ones. Inferring non-stochastic grammars, only, is dealt with, but given a non-stochastic grammar it is much easier to infer the production probabilities than to infer these from some random startpoint. Hence, the method can greatly speed up the inference of stochastic grammars. The main limitation is the exponential growth with respect to pattern length. Nonetheless, results show how traditional toy problems such as parity and palindrome languages can be learned much more quickly than with previous methods. Ways of overcoming the exponential growth are discussed. ESA

DISCERN: A DISTRIBUTED NEURAL NETWORK MODEL OF SCRIPT PROCESSING AND MEMORY

Risto Miikkulainen *In* Univ. Twente, Connectionism and Natural Language Processing Oct. 1992 p 115-124 Sponsored in part by ITA Foundation; Academy of Finland; Emil Aaltonen Foundation, Finland; Foundation for the Advancement of Technology; Alfred Kordelin Foundation, Finland (For primary document see N94-20242 05-63)

Copyright Avail: CASI HC A02/MF A02

DISCERN (Distributed Script processing and Episonic memory Network), a large scale natural language processing system built entirely from distributed neural networks, is addressed. DISCERN reads short narratives about stereotypical event sequences, stores them in episodic memory, generates fully expanded paraphrases of the narratives, and answers questions about them. Processing in DISCERN is based on hierarchically

organized backpropagation modules, communicating through a central lexicon of word representations. The lexicon is a double feature map system that transforms each orthographic word symbol in its semantic representation and vice versa. The episodic memory is a hierarchy of feature maps, where memories are stored 'one-shot' at different locations. Several high level phenomena emerge automatically from the special properties of distributed neural networks. DISCERN learns to infer unmentioned events and unspecified role fillers, and it generates expectations and defaults and exhibits plausible lexical access errors and memory interference behavior. Word semantics, memory organization, and appropriate script inferences are automatically extracted from examples. ESA

TELEOPERATION WITH VIRTUAL FORCE FEEDBACK
R. J. Anderson 1993 8 p Presented at the Society of Photo-Optical Instrumentation Engineer's (SPIE) International Symposium on Optical Tools for Manufacturing and Advanced Automation, Boston, MA, 7-10 Sep. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019406; SAND-93-1914C; CONF-9309199-2) Avail: CASI HC A02/MF A01

In this paper we describe an algorithm for generating virtual forces in a bilateral teleoperator system. The virtual forces are generated from a world model and are used to provide real-time obstacle avoidance and guidance capabilities. The algorithm requires that the slaves tool and every object in the environment be decomposed into convex polyhedral Primitives. Intrusion distance and extraction vectors are then derived at every time step by applying Gilbert's polyhedra distance algorithm, which has been adapted for the task. This information is then used to determine the compression and location of nonlinear virtual spring-dampers whose total force is summed and applied to the manipulator/teleoperator system. Experimental results validate the whole approach, showing that it is possible to compute the algorithm and generate realistic, useful pseudo forces for a bilateral teleoperator system using standard VME bus hardware. This invention is a novel high-speed neural network based processor for solving the 'traveling salesman' and other global optimization problems. It comprises a novel hybrid architecture employing a binary synaptic array whose embodiment incorporates the fixed rules of the problem, such as the number of cities to be visited. The array is prompted by analog voltages representing variables such as distances. The processor incorporates two interconnected feedback networks, each of which solves part of the problem independently and simultaneously, yet which exchange information dynamically. Neural networks are computing systems modeled after the paradigm of the biological brain. For years, researchers using various forms of neural networks have attempted to model the brain's information processing and decision-making capabilities. Neural network algorithms have impressively demonstrated the capability of modeling spatial information. On the other hand, the application of parallel distributed models to the processing of temporal data has been severely restricted. The invention introduces a novel technique which adds the dimension of time to the well known back-propagation neural network algorithm. In the space-time neural network disclosed herein, the synaptic weights between two artificial neurons (processing elements) are replaced with an adaptable-adjustable filter. Instead of a single synaptic weight, the invention provides a plurality of weights representing not only association, but also temporal dependencies. In this case, the synaptic weights are the coefficients to the adaptable digital filters. Novelty is believed to lie in the disclosure of a processing element and a network of the processing elements which are capable of processing temporal as well as spacial data.

DEVELOPMENT AND TESTING OF A RELIABILITY PERFORMANCE INDEX FOR MODULAR ROBOTIC SYSTEMS Final Report
Dean L. Schneider, Delbert Tesar, and J. W. Barnes Oct. 1993 10 p
(AD-A271901; AFIT/EN/TR-93-08) Avail: CASI HC A02/MF A01

Using a probabilistic representation of manipulator kinematics and a reliability block diagram model of the manipulator system, a Reliability Performance Index (RPI) representing the probability of no hardware or software failure and the manipulator achieving a specified position and orientation is developed. The RPI is tested with a case study consisting of a three degree-of-freedom planar manipulator assembled from a choice of six joint modules of varying reliability and precision and a choice of six link module combinations of varying lengths and machining tolerances. A straight-line, square trajectory is specified and the RPI is calculated for each combination of joint modules and links, a total of 1296 different combinations. Using statistical testing, a 70% reduction in the module design space is achieved using the RPI. Optimization using other appropriate manipulator criteria can then be performed to generate the final configuration. Additional extensive case studies are needed to fully develop the RPI to a stage necessary for implementation into a computer-aided design system for modular robot configuration design. The RPI may also be useful in the quantification of the overall system reliability and performance of any system based upon measured error, such as control systems. DTIC

SIMULATING A USER'S PREFERENCES: TOWARDS AUTOMATED ARTIFICIAL EVOLUTION FOR COMPUTER GENERATED IMAGES
Shumeet Baluja, Dean Pomerleau, and Todd Jochem 14 Oct. 1993 31 p
(Contract N00014-93-1-0806)
(AD-A272058; CMU-CS-93-198) Avail: CASI HC A03/MF A01

In 1991, Karl Sims presented work on artificial evolution in which he used genetic algorithms to evolve complex structures for use in computer generated images and animations. The evolution of the computer generated images progressed from simple, randomly generated shapes to interesting images which the users interactively created. The evolution advanced under the constant guidance and supervision of the user. This paper describes attempts to automate the process of image evolution through the use of artificial neural networks. The central objective of this study is to learn the user's preferences, and to apply this knowledge to evolve aesthetically pleasing images which are similar to those evolved through interactive sessions with the user. This paper presents a detailed analysis of both the shortcomings and successes encountered in the use of five artificial neural network architectures. Further possibilities for improving the performance of a fully automated system are also discussed. DTIC

Neural information processing has already helped catalyzed many potential opportunities of cross-fertilization, from which many diversified disciplines have benefited mutually. However, in order to substain a long-term impact, there must establish a fundamental and coherent theory for it. This project focuses on the development and understanding of the fundamental system theoretical basis for temporal dynamic networks. The main thrust of the research hinges on a thorough understanding of several key issues regarding temporal dynamical system modeling, including model unification, training efficiency, generalization performance, and hierarchical network structure. A typical robot vision scenario might involve a vehicle moving with an unknown 3D motion (translation and rotation) while taking intensity images of an arbitrary environment. This paper describes the theory and implementation issues of tracking any desired point in the environment. This method is performed completely in software without any need to mechanically move the camera relative to the vehicle. This tracking technique is simple and inexpensive. Furthermore, it does not use either optical flow or feature correspondence. Instead, the spatio-temporal gradients of the input intensity images are used directly. The experimental results presented support the idea of tracking in software. The final result is a sequence of tracked images where the desired point is kept stationary in the images independent of the nature of the relative motion. Finally, the quality of these tracked images are examined using spatio-temporal gradient maps. DTIC

A scheme for recognizing 3D objects from single 2D images is introduced. The scheme proceeds in two stages. In the first stage, the categorization stage, the image is compared to prototype objects. For each prototype, the view that most resembles the image is recovered and, if the view is found to be similar to the image, the class identity of the object is determined. In the second stage, the identification stage, the observed object is compared to the individual models of its class, where classes are expected to contain objects with relatively similar shapes. For each model, a view that matches the image is sought. If such a view is found, the object's specific identity is determined. The advantage of categorizing the object before it is identified is twofold. First, the image is compared to a smaller number of models, since only models that belong to the object's class need to be considered. Second, the cost of comparing the image to each model in a class is very low, because correspondence is computed once for the whole class. More specifically, the correspondence and object pose computed in the categorization stage to align the prototype with the image are reused in the identification stage to align the individual models with the image. As a result, identification is reduced to a series of simple template comparisons. The paper concludes with an algorithm for constructing optimal prototypes for classes of objects. DTIC

(AD-A271769; NAWCADWAR-93041-60) Avail: CASI HC A04

A method of estimating the rotor position of a switched reluctance machine without the need for a rotor-mounted position sensor has been developed. This method takes advantage of the information derived from known phase voltage and current waveforms. The information is fed as the inputs to a neural network, which after being trained, can correctly map the rotor position to its output. The most accurate mapping results were obtained using a Cerebellar Model Articulation Controller (CMAC) neural network. The performance of the neural network has been tested with measured waveforms from a three phase 120 HP switched reluctance motor. It successfully maps the rotor position with an average root mean square error of one tenth of a mechanical degree. DTIC

THE CORRELATED M/G/1 QUEUE
O. J. Boxma and M. B. Combe Jan. 1993 14 p Sponsored by NFI, Netherlands
(CWI-BS-R9303; ETN-94-94720) Copyright Avail: CASI HC A03/MF A01

A single server queue in which the service time of each customer depends on the length of the preceding interarrival interval is considered. The dependence structure corresponds to the situation where work arrives at a gate according to a process with independent increments, while at exponential intervals the gate is opened and, after the addition of an independent component, the work is delivered to the server as a single

customer. This model unifies and generalizes other recently studied M/G/1 queues with dependence between interarrival and service times. The main result is the joint steady state distribution of the waiting and service time of a customer. As a by-result, the sojourn time distribution is obtained; a decomposition for its Laplace-Stieltjes transform is presented and interpreted. ESA

GRAPHICAL INTERACTIVE PLANNING OF ROBOTIC APPLICATIONS WITH SUPPORT OF INTEGRATED SIMULATION Ph.D. Thesis [GRAPHISCH-INTERAKTIVE PLANUNG VON ROBOTIKANWENDUNGEN MIT UNTERSTUETZUNG INTEGRIERTER SIMULATION]

Fan Dai 1991 184 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ETN-93-93793) Avail: CASI HC A09

A general concept of a planning system in a graphical interactive environment is developed. An object model was used for describing work wells. The action model describes activities in a robot work cell as time dependent variations of the object properties. Operations are connected with one another through conditions. Graphical elements are used for general description of graphical information. Representation forms and manipulation features are taken into account. These models are attempted to guarantee the flexibility of the method. Abstract iterations describe, on the basis of object, classes, functional processes which are independent on work cells and can be performed by parameterization of actions of several work cells. The motion planning is considered as a part of the concrete operation planning. The simulation of planned processes is considered as a running operation and its integration is obtained in all phases of planning. The universal connection between planning components, needed for their integration, can be performed by using a knowledge basis, which contains descriptions of concrete objects. Visualization and manipulations of actions and objects are general functions, which can be integrated in the central interaction control. ESA

INTERACTIVE SIMULATION PACKAGE FOR COUPLED BENDING AND TORSIONAL VIBRATIONS IN FLEXIBLE ROBOT ARMS

M. Vajta, Z. Pocz, and A. Bagchi Oct. 1992 9 p Presented at the 11th IASTED International Conference on Modelling, Identification and Control, Innsbruck, Austria, 10-12 Feb. 1992 Sponsored by IASTE Limited Reproducibility: More than 20% of this document may be affected by poor print

(MEMO-1089; ETN-93-94129) Avail: Issuing Activity (European Space Agency (ESA))

A dynamic model of coupled bending and torsional vibrations in flexible robot arms is described. Coupling is almost unavoidable due to the asymmetricity of the payload. The basic model is a Euler-Bernoulli beam with Voigt type of internal damping. Different damping coefficients were assumed in bending and in torsion, respectively. An interactive simulation package to analyze these vibrations is also described. Time domain analysis with different methods is detailed. Numerical examples of a beam used in laboratory experiments are also given. ESA

ON THE OPTIMALITY OF FCFS FOR NETWORKS OF MULTI-SERVER QUEUES

Ger Koole Dec. 1992 15 p

(Grant CEC-DG-XIII-BRA-QMIPS)

(CWI-BS-R9235; ETN-94-94713) Copyright Avail: CASI HC A03/MF A01

Multiserver queues in which arriving customers can be assigned to different servers are considered. For three models the optimality of assigning customers to the server with smallest workload, FCFS (First Come First Served), is obtained. In the first two models, isolated queues are studied. The difference is that in the first the cost functions are related to the workload and in the second, the departure processes are compared. The third model is concerned with networks of multiserver queues. ESA

LECTURE NOTES IN ARTIFICIAL INTELLIGENCE 689: THE 7TH INTERNATIONAL SYMPOSIUM ON METHODOLOGIES FOR INTELLIGENT SYMPOSIUM (ISMIS 1993)

J. Komorowski, ed. and Z. W. Ras, ed. 18 Jun. 1993 664 p Symposium held in Trondheim, Norway, Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-93-1-0244)

(AD-A271768) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This volume contains papers which were selected for presentation at the Seventh International Symposium on Methodologies for Intelligent Systems - ISMIS'93, held in Trondheim, Norway, 15-18 June 1993. The Organizing Committee selected the following major areas for ISMIS'93: approximate reasoning, constraint programming; expert systems; intelligent databases; knowledge representation; learning and adaptive systems; manufacturing; and methodologies. N PARALLEL QUEUEING SYSTEMS WITH SERVER BREAKDOWN AND REPAIR

Pieter Wartenhorst Dec. 1992 35 p

(CWI-BS-R9236; ETN-94-94715) Copyright Avail: CASI HC A03/MF A01

A model that can be used to study the influence of machine breakdown and limited repair capacity on the performance of a system that has to provide service continuously is presented. A system consisting of N single server queueing stations, each serving its own stream of customers, is considered. The servers of the stations are subject to breakdown. Broken servers are repaired by a joint repair facility consisting of K parallel repairmen. Whenever K is less than N, the repair facility is causing interference between the N stations. The behavior of the queue length at a particular station (say station 1) is studied in the long run. By modeling station 1 as an M/M/1 queue in a Markovian environment, an exact matrix geometric solution for the marginal queue length distribution and for the distributions of the queue length at the beginning of an up (down) period of the server is obtained. Since the matrix geometric solution becomes rather time and memory consuming when N is large, approximating closed form expressions are also developed. By assuming the lengths of subsequent down periods to be independent, station 1 is approximated by an M/M/1 queue with independent interruptions. Stochastic decompositions are employed to obtain approximations for the queue length distributions. With this model several design issues can be investigated such as the number of repairmen that is needed to maintain a certain pool of machines, or the number of machines that can be assigned to a certain crew of repairmen. Several numerical examples illustrate how the queue at station 1 is afffected by breakdowns of server 1 and by the other stations due to congestion at the repair facility. ESA

OPTIMIZATION OF FIXED TIME POLLING SCHEMES
S. C. Borst, O. J. Boxma, J. H. A. Harink, and G. B. Huitema (PTT Telecommunicatie, Groningen, Netherlands.) Dec. 1992 27 p
(Grant CEC-DG-XIII-BRA-QMIBS)
(CWI-BS-R9237; ETN-94-94716) Copyright Avail: CASI HC A03/MF A01

The problem of deriving efficient operational rules for polling queues according to a fixed time polling scheme is addressed. A fixed time polling scheme specifies the visit order of the queues, but also the starting times for each visit. This problem arose from the need to efficiently collect files with call records from telecommunication switches. Using a simple approximation for the mean waiting times in a polling system with a non-cyclic visit order of the queues, an approach to the problem of minimizing a weighted sum of the mean waiting times at the various queues is presented. This approach is tested via numerical experiments that are partly based on actual data for call records. ESA

AN EVALUATION OF ARTIFICIAL NEURAL NETWORK MODELING FOR MANPOWER ANALYSIS M.S. Thesis
Brian J. Byrne Sep. 1993 145 p
(AD-A273001) Avail: CASI HC A07/MF A02

This thesis evaluates the capabilities of artificial neural networks in forecasting the take-rates of the Voluntary Separations Incentive/Special Separations Benefit (VSI/SSB) programs for male, Marine Corps Enlisted Personnel in the grades of E-5 and E-6. The Artificial Neural Networks models are compared with the forecasting abilities of a classical regression model. The data are taken from the Headquarters Marine Corps Enlisted Master File which contains military and personal background on each enlisted member of the United States Marine Corps. The classical regression model is a casual model constructed based upon the theory of occupational job choice. The neural network models are presented with all available data elements. Empirical results indicate that artificial neural networks provide forecasting results at least as good as, if not better than, those obtained using classical regression techniques. However, artificial neural networks are limited in their usefulness for policy analysis. DTIC

IMPLEMENTING ELECTRONIC DATA INTERCHANGE (EDI) WITH SMALL BUSINESS SUPPLIERS IN THE PRE-AWARD ACQUISITION PROCESS M.S. Thesis
Robert B. Sergeson Jun. 1993 106 p
(AD-A271767) Avail: CASI HC A06/MF A02

This thesis examines the implementation of electronic data interchange (EDI) with small business suppliers in the pre-award acquisition process. The general history and concept of EDI is discussed along with the pre-award acquisition process. The results of a small business survey are analyzed to provide insight on the barriers and impediments to implementing EDI with small business concerns. Additionally, interviews and discussions with major corporations were conducted to identify common lessons learned by these corporations in their efforts to implement EDI with their small business supplier base. The major conclusion drawn is that DoD can successfully implement EDI with its small business supplier base in the preaward acquisition process. It was determined that the following key factors are crucial to successful implementation of EDI with small business: provide effective training; specifically direct grant funding to the Procurement Technical Assistance Centers; require the Small Business Administration to aggressively sponsor and implement EDI training; draft legislation to modify or eliminate restrictive laws and regulations; and foster the use of Value-Added Networks, Trading Partner Agreements, and EDI Service Bureaus. These efforts would provide the basic infrastructure to enable DoD to train, nurture, and help problem solve with small businesses once DoD becomes totally reliant upon EDI. DTIC

GOAL-ORIENTED DYNAMIC VISION
Peter A. vonKaenel, Christopher M. Brown, and Raymond D. Rimey Aug. 1993 31 p
(Contract MDA972-92-J-1012; NSF CDA-88-22724; NSF IRI-89-20771)
(TR-466) Avail: CASI HC A03/MF A01

TEA-1 is a selective vision system that uses Bayes nets for representation and benefit-cost analysis for control of visual and nonvisual actions. TEA-1 solves T-world problems, a class of problems involving static two-dimensional scenes. For example, TEA-1 was demonstrated to answer questions about scenes of dinner tables. dTEA-1, an extension to TEA-1 that allow tasks to be performed on dynamic scenes, is presented. Currently, dTEA-1 successfully performs a task on a simulated train scene. The objects in the scene include a train on a track and a herd of cows, but the domain may be extended to include static objects and other classifications of moving objects. The task is to keep track of the locations of objects, and the system intelligently allocates its effort to keep uncertainty and cost to a minimum. Author (revised)

HIGH DIMENSION ACTION SPACES IN ROBOT SKILL LEARNING
Jeff G. Schneider May 1993 22 p
(Contract MDA972-92-J-1012)
(TR-458) Avail: CASI HC A03/MF A01

Table lookup with interpolation is used for many learning and adaptation tasks. Redundant mappings capture the important concept of 'motor skill,' which is important in real, behaving systems. Few, if any, robot skill implementations have dealt with redundant mappings, in which the space to be searched to create the table has much higher dimensionality than the table itself. A practical method for inverting redundant mappings is important in physical systems with limited time for trials. The 'Guided Table Fill In' algorithm, which uses data already stored in the table to guide search through the space of potential table entries, is presented. The algorithm is illustrated and tested on a robot skill learning task both in simulation and on a robot with a flexible link. Our experiments show that the ability to search high dimensional action spaces efficiently allows skill learners to find new behaviors that are qualitatively different from what they were presented or what the system designer may have expected. Thus the use of this technique can allow researchers to seek higher dimensional action spaces for their systems rather than constraining their search space at the risk of excluding the best actions. SIMULATION OF TRIPOD GAITS FOR A HEXAPOD UNDERWATER WALKING MACHINE M.S. Thesis
Charles A. Schue, III Jun. 1993 270 p
(AD-A271719) Avail: CASI HC A12/MF A03

This thesis develops the mathematical relationships necessary to implement alternating tripod gaits on the hexapod underwater walking machine, AquaRobot. Analysis of documentation and application of Denavit-Hartenberg kinematic modeling techniques determine the fundamental vehicle parameters. Smooth leg motion models following elliptical and cycloidal trajectories are devised. Gait planning algorithms, using the elliptical smooth leg motion model, are developed for both discrete and continuous body motion. Statically stable, alternating tripod gait simulations are implemented in the C + + programming language. A stick figure graphics display allows examination and testing of the gait algorithms prior to incorporation in follow-on 3D graphics simulations or in real-time operation. DTIC

APPLICATION OF A BACK-PROPAGATION NEURAL NETWORK TO ISOLATED-WORD SPEECH RECOGNITION M.S. Thesis
Chau G. Le Jun. 1993 44 p
(AD-A272495) Avail: CASI HC A03/MF A01

The primary objective of this research is to explore how a back-propagation neural network (BNN) can be applied to isolated-word speech recognition. Simulation results show that a BNN provides an effective approach for small vocabulary systems. The recognition rate reaches 100% for a 5-word system and 94% for a 10-word system. The general techniques developed can be further extended to other applications, such as sonar target recognition, missile seeking and tracking functions in modern weapon systems, and classification of underwater acoustic signals. SECURITY EVALUATION OF UNIX NETWORKS M.S. Thesis

Thomas L. Brown Sep. 1993 127 p
(AD-A273076) Avail: CASI HC A07/MF A02

In recent years, computer networks have significantly increased in both complexity and number, and these networks are attractive targets for attack and intrusion. Unix networks being managed by the government and providing access to unclassified sensitive information are particularly vulnerable to attack. Ensuring the security of sensitive information will be one of the single most important management issues in computer/information security in the foreseeable future. Unfortunately, the number of automated security tools for Unix, as well as the number of computer security experts within DOD, has not increased sufficiently to keep up with the improvements in technology. The author proposes the concept of a security toolbox, containing a proposed standard set of automated security tools, to support Unix networks. The toolbox can be used to enhance system security automating many of the security related tasks required of the network administrator. Additionally, organizational changes will be necessary to improve the availability of computer security advice and assistance. It is recommended that a study of the function and organization of computer security expertise be conducted, so that access to and validation of security tools, along with consistent guidance for network administrators and security officers, can be accomplished effectively. The combination of a security toolbox and expert advice can then help bridge the gap in the development of computer security expertise. DTIC

MODEL-BASED AUTOMATIC GENERATION OF GRASPING REGIONS
David A. Bloss 1 Dec. 1993 13 p
(NASA-TM-104785; S-745; NAS 1.15:104785) Avail: CASI HC A03/MF A01

The problem of automatically generating stable regions for a robotic end effector on a target object, given a model of the end effector and the object is discussed. In order to generate grasping regions, an initial valid grasp transformation from the end effector to the object is obtained based on form closure requirements, and appropriate rotational and translational symmetries are associated with that transformation in order to construct a valid, continuous grasping region. The main result of this algorithm is a list of specific, valid grasp transformations of the end effector to the target object, and the appropriate combinations of translational and rotational symmetries associated with each specific transformation in order to produce a continuous grasp region. TANDEM QUEUES WITH DETERMINISTIC SERVICE TIMES
O. J. Boxma and J. A. C. Resing (Technische Univ., Eindhoven, Netherlands.) Dec. 1992 20 p
(Grant CEC-DG-XIII-BRA-QMIPS)
(CWI-BS-R9238; ETN-94-94717) Copyright Avail: CASI HC A03/MF A01

A tandem queueing model for a sequence of multiplexers at the edge of an ATM (Asynchronous Transfer Mode) network is considered. All queues of the tandem queueing model have unit service times. Each successive queue receives the output of the previous queue plus some external arrivals. For the case of two queues in series, the end to end delay of a cell (customer) arriving at the first queue, and the covariance of its delay at both queues, are studied. The joint queue length process at all queues is studied in detail for the two and three queue cases and an approach to the case of an arbitrary number of queues in series is outlined. ESA

OPTIMIZATION AND CONTROL OF A SMALL ANGLE ION SOURCE USING AN ADAPTIVE NEURAL NETWORK CONTROLLER
S. K. Brown, W. C. Mead, P. S. Bowling, R. D. Jones, and C. W. Barnes 1993 17 p Presented at the 5th International Conference on Ion Sources, Peking, China, 31 Aug. - 4 Sep. 1993
(Contract W-7405-eng-36)
(DE93-040063; LA-UR-93-2908; CONF-9308136-3) Avail: CASI HC A03/MF A01

This project developed an automated controller based on an artificial neural network and evaluated its applicability in a real-time environment. This capability was developed within the context of a small angle negative ion source on the Discharge Test Stand at Los Alamos. The controller processes information obtained from the beam current waveform developing a figure of merit (fom) to determine the ion source operating conditions. The fom is composed of the magnitude of the beam current, the stability of operation, and the quietness of the beam. Using no knowledge of operating conditions, the controller begins by making a rough scan of the four-dimensional operating surface. This surface uses as independent variables the anode and cathode temperatures, the hydrogen flow rate, and the arc voltage. The dependent variable is the fom described above. Once the rough approximation of the surface has been determined, the network formulates a model from which it determines the best operating point. The controller takes the ion source to that operating point for a reality check. As real data is fed in, the model of the operating surface is updated until the neural network's model agrees with reality. The controller then uses a gradient ascent method to optimize the operation of the ion source. Initial tests of the controller indicate that it is remarkably capable. It has optimized the operation of the ion source on six different occasions bringing the beam to excellent quality and stability. DOE

ROBOTIC CONCEPTS FOR OPERATION IN BARREN TERRAIN
K. Dowling (Carnegie-Mellon Univ., Pittsburgh, PA.) Jan. 1993 24 p
(Contract W-7405-eng-48)
(DE93-040539; UCRL-CR-114855) Avail: CASI HC A03/MF A01

We have performed a series of studies and configurations for robots that are capable of operating in rough barren terrains. The environments we are targeting are like those of the moon or other planets in the roughness and starkness of the terrains, the loose and hard materials that range from sandy slopes to boulder fields, and the extremes of temperature that are encountered in such places. We present a mission scenario and requirements and then present and evaluate a mechanism design. Additional subsystem issues of power, communication, sensing, and computing are all addressed with respect to these requirements. DOE

(DE93-040753; SAND-93-1468C; CONF-9308171-1) Avail: CASI HC A02/MF A01

The US Department Energy's Office of Technology Development has sponsored the development of generic robotics technologies for application to a wide range of remote systems. Of primary interest is the development of technologies which enable faster, safer, and cheaper cleanup of hazardous waste sites than is possible using conventional human contact or remote manual approaches. The development of model-based sensor-directed robot control approaches supports these goals by developing modular control technologies which reduce the time and cost of development by allowing reuse of control system software. In addition, the use of computer models improves the safety of remote site cleanup by allowing automated errors detection and recovery while reducing the time for technology development. DOE

Fuzzy logic and neural networks provide new methods for designing control systems. Fuzzy logic controllers do not require a complete analytical model of a dynamic system and can provide knowledge-based heuristic controllers for ill-defined and complex systems. Neural networks can be used for learning control. In this chapter, we discuss hybrid methods using fuzzy logic and neural networks which can start with an approximate control knowledge base and refine it through reinforcement learning. Author

GENERAL ASYMMETRIC NEURAL NETWORKS AND STRUCTURE DESIGN BY GENETIC ALGORITHMS: A LEARNING RULE FOR TEMPORAL PATTERNS
S. Bornholdt (Heidelberg Univ., Germany.) and D. Graudenz Jul. 1993 14 p
(Contract DE-AC03-76SF-00098)
(DE94-001254; LBL-34384; HD-THEP-93-26) Avail: CASI HC A03/MF A01

This paper demonstrates that genetic algorithms provide a learning rule for general asymmetric neural nets which is suited for learning temporal patterns without any assumptions on the topology of the emerging network. The learning capability has been demonstrated with a five bit parity problem for a static diluted neural net. The successful training of a counting neural network shows the ability of the learning rule to choose the weights in a way that leads to feedback loops in the neural network that store the information necessary for counting. This mechanism turns out to be robust against asymmetric update of the neural network. Genetic algorithms are shown to be useful for training and choosing the weights of neural networks where standard learning rules fail. Derived from text

The occupancy grid method (OGM), a probabilistic spatial modelling technique, was developed for handling a world where a robot is the only moving object. Since this method lacks the ability to predict the location of moving objects over time, the OGM was extended to handle objects moving at constant velocity. A four dimensional location velocity space is subdivided into cells, each of which is associated with a probability of an object existing at that location moving at that velocity. This probabilistic information is updated over time using the Bayesian reasoning formula. Two pieces of probabilistic information are considered in calculating such a probability: one indicating the likelihood that there are objects at that location and the other the likelihood that an object at a given location moves with a particular velocity. Methods are presented for deriving the probability for each cell in the extended occupancy grid by combining the original OGM with motion detection mechanisms such as the Hough transform. The latter approach is robust in the case of occlusion, and can be easily extended to handle other motions such as rotation and acceleration. Author (CISTI)

REPRESENTATION AND RECOGNITION WITH ALGEBRAIC INVARIANTS AND GEOMETRIC CONSTRAINT MODELS Progress Report, 1 Mar. - 1 Jun. 1993
Joseph L. Mundy 7 Sep. 1993 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA972-91-C-0053; ARPA Order 8228)
(AD-A271395) Avail: CASI HC A02

This document reports progress on the subject project from 3/1/93 to 6/1/93. A new approach to epipolar calibration has been implemented which provides a coordinate framework for relating features across multiple views. The invariant object recognition system has been successfully demonstrated on RADIUS model board imagery. The approach reported last quarter for the extraction of Euclidean structure has been implemented and initial results are promising. DTIC

STOCHASTIC OPTIMIZATION BY SIMULATION: NUMERICAL EXPERIMENTS WITH M/M/1 QUEUE IN STEADY-STATE
Peter W. Glynn, Nataly Giroux, and Pierre LEcuyer Jul. 1993 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0101)
(AD-A271143; SU-TR-93-13; ARO-28809.16-MA-SDI) Avail: CASI HC A03

This paper gives numerical illustrations of the behavior of stochastic approximation combined with different derivative estimation techniques, to optimize a steady-state system. It is a companion paper to L'Ecuyer and Glynn, which gives convergence proofs for most of the variants experimented with here. The numerical experiments are made with a simple M/M/1 queue, which while simple, serves to illustrate the basic convergence properties and possible pitfalls of the various techniques. DTIC

In this paper we consider the numerical solution of higher-index differential algebraic equations with ill-conditioned or rank-deficient constraints. These types of problems arise for example in the solution of constrained mechanical systems, when a mechanism's trajectory passes through or near a kinematic singularity. We derive a class of methods for these problems which are based on minimization of the norm of the constraints. The new methods are analogous to trust-region methods of numerical optimization. We give error estimates and convergence and stability results for the new methods, and present SCM numerical experiments which illustrate their effectiveness. DTIC

LITERATURE REVIEW OF THE ERRORS-IN-VARIABLES APPROACH TO THE PROBLEM OF SYSTEM IDENTIFICATION
Betty Emslie Jul. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271098; ARL-TN-42; DODA-007-097) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The papers reviewed here deal with various aspects of the problem of system identification when all the observed variables are contaminated by noise errors. Theoretical issues of identifiability and practical methods for developing algorithms to estimate parameters of a dynamic system are considered. The total least squares approach and the Koopmans-Levin method are among the methods discussed. Both these methods are strongly based on matrix singular value decomposition, which is a computationally robust numerical technique. A book, which is a compilation of papers originating from a workshop on singular value decomposition and signal processing is included in the references. DTIC

ARE TYPES NEEDED FOR NATURAL LANGUAGE?
F. Kamareddine 1992 42 p See also PB93-191823 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191831; COMPUTING SCIENCE NOTES-92/20) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The type free lambda-calculus is powerful enough to contain all the polymorphic and self-referential nature of properties. Logic, however, due to the paradoxes, is absent from the type free lambda-calculus. This makes such a calculus an unsuitable device for Natural Language Semantics. Moreover, the problems that arise from mixing the type free Lambda-calculus with logic lead to type theory and hence formalization of Natural Language were carried out in a strictly typed framework. The paper embeds the typing system into one which gives an interpretation of Parsons system in a type free theory where logic is present. In other words, it takes the standpoint that type freeness is needed yet types are also indispensable. On this ground, by constructing types in the type free theory, it obtains a framework which can be seen as a formalization of Parsons' claim that Natural Language needs type freeness in order to accommodate self referentiality yet many sentences should be understood as implicitly typed. MATHEMATICS B FOR THE STUDY DIRECTION VWO: A RECONNAISSANCE [WISKUNDE B VWO: EEN VERKENNING]
Annette Lievaart 1992 63 p In DUTCH
(Rept-92-80; ETN-93-94273) Copyright Avail: CASI HC A04/MF A01

The revised program Mathematics B for secondary schools (VWO) students who want a higher education in a technical or exact sciences direction is criticized. The aim is to improve the efficiency of the education of mathematics engineers by a better connection between the program of secondary schools and that of universities. The mathematics program of the VWO contains analysis and geometry and emphasizes calculation skills and not the theoretical background. The program is overloaded whereby too little time is left to refresh the basic knowledge from time to time. Theory and practice are not always in accordance. ESA

A NEW CONFORMAL ABSORBING BOUNDARY CONDITION FOR FINITE ELEMENT MESHES AND PARALLELIZATION OF FEMATS
A. Chatterjee, J. L. Volakis, J. Nguyen, M. Nurnberger, and D. Ross Dec. 1993 69 p
(Grant NAG2-866)
(NASA-CR-194740; NAS 1.26:194740; UMICH-031155-1-T) Avail: CASI HC A04/MF A01

Some of the progress toward the development and parallelization of an improved version of the finite element code FEMATS is described. This is a finite element code for computing the scattering by arbitrarily shaped three dimensional surfaces composite scatterers. The following tasks were worked on during the report period: (1) new absorbing boundary conditions (ABC's) for truncating the finite element mesh; (2) mixed mesh termination schemes; (3) hierarchical elements and multigridding; (4) parallelization; and (5) various modeling enhancements (antenna feeds, anisotropy, and higher order GIBC). ON THE SPLINE-BASED WAVELET DIFFERENTIATION MATRIX Final Report
Leland Jameson Nov. 1993 38 p Submitted for publication
(Contracts NAS1-19480; N00014-91-C-4016; NSF DMS-92-11820; AF-AFOSR-0090-93; RTOP 505-90-52-01)
(NASA-CR-191557; NAS 1.26:191557; ICASE-93-80) Avail: CASI HC A03/MF A01

The differentiation matrix for a spline-based wavelet basis is constructed. Given an n-th order spline basis it is proved that the differentiation matrix is accurate of order $2n + 2$ when periodic boundary conditions are assumed. This high accuracy, or superconvergence, is lost when the boundary conditions are no longer periodic. Furthermore, it is shown that spline-based bases generate a class of compact finite difference schemes. Author (revised)

SHAPE OPTIMIZATION GOVERNED BY THE EULER EQUATIONS USING AN ADJOINT METHOD Final Report
Angelo Iollo, Manuel D. Salas (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.), and Shlomo Taasan Nov. 1993 21 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191555; NAS 1.26:191555; ICASE-93-78) Avail: CASI HC A03/MF A01

A numerical approach for the treatment of optimal shape problems governed by the Euler equations is discussed. Focus is on flows with embedded shocks. A very simple problem is considered: the design of a quasi-one-dimensional Laval nozzle. A cost function and a set of Lagrange multipliers are introduced to achieve the minimum. The nature of the resulting costate equations is discussed. A theoretical difficulty that arises for cases with embedded shocks is pointed out and solved. Finally, some results are given to illustrate the effectiveness of the method. Author (revised)

ON MULTIFLOW PROBLEMS
Andras Frank (Bonn Univ., Germany.), Alexander Karzanov (Institute for System Studies, Moscow, USSR.), and Andras Sebo Apr. 1992 20 p Sponsored in part by Mairie de Grenoble, France
(RR-889-M; ETN-93-94981) Avail: CASI HC A03/MF A01

Some relationships between multicommodity flow problems are revealed. These are various versions of the multicommodity flow problems such as edge demand, node demand, maximization, and locking problems. With an unexpected use of Edmonds' polymatroid intersection theorem, a theorem of Karzanov and Lomonosov on multiflow maximization is derived. The approach gives rise to a combinatorial polynomial time algorithm to find the maximum in question. A certain weighted version of the maximization problem also becomes tractable. ESA

DETERMINING THE DISTANCE TO THE PERFECT MATCHING POLYTOPE OF A BIPARTITE GRAPH
Andras Frank (Bonn Univ., Germany.) and Alexander V. Karzanov Jun. 1992 10 p Sponsored by Mairie de Grenoble, France
(RR-895-M; ETN-93-94986) Avail: CASI HC A02/MF A01

The problem of finding the euclidean distance from the origin to the perfect matching polytope of a bipartite graph is considered. Being a quadratic program with linear constraints, this problem can be solved in polynomial time by use of a version of the ellipsoid method. A combinatorial algorithm which solves it in polynomial time is developed. The algorithm as well as the proof of its correctness uses ideas involved in the cancelling minimum mean circuit algorithm for the minimum cost circulation problem due to Goldberg and Tarjan. ESA

ON THE NUMERICAL STABILITY OF QUASI-DEFINITE SYSTEMS
P. E. Gill, J. R. Shinnerl, and M. A. Saunders Jun. 1993 9 p
(Contract DE-FG03-92ER-25117)
(DE93-019404; SU-SOL-93-4) Avail: CASI HC A02/MF A01

The authors discuss the solution of sparse linear equations $Kd = r$, where K is a symmetric and specially structured indefinite matrix that often arises in numerical optimization. For such K, the indefinite factorization $K = LDL(\text{sup } T)$ is known to exist in exact arithmetic with 1 x 1 pivots and no row or column interchanges. It is shown that the stability of the $LDL(\text{sup } T)$ factorization of this matrix is naturally connected with the stability of the $LDM(\text{sup } T)$ factorization of a closely related unsymmetric positive-definite matrix. Conditions are given that allow the stable numerical solution of this system by Gaussian elimination without row and column interchanges. DOE

PARALLEL BAND REDUCTION AND TRIDIAGONALIZATION
C. Bischof, X. Sun, and M. Marques (Texas Univ., Austin.) 1993 8 p Presented at the 6th Society for Industrial and Applied Mathematics (SIAM) Conference on Parallel Processing for Scientific Computing, Norfolk, VA, 21-24 Mar. 1993
(Contract W-31-109-eng-38)
(DE93-019566; ANL/MCS/CP-80518; CONF-930331-15) Avail: CASI HC A02/MF A01

This paper presents a parallel implementation of a blocked band reduction algorithm for symmetric matrices suggested by Bischof and Sun. The reduction to tridiagonal or block tridiagonal form is a special case of this algorithm. A blocked double torus wrap mapping is used as the underlying data distribution and the so-called WY representation is employed to represent block orthogonal transformations. Preliminary performance results on the Intel Delta indicate that the algorithm is well-suited to a MIMD computing environment and that the use of a block approach significantly improves performance. NEOCLASSICAL KINETIC THEORY NEAR AN X-POINT: PLATEAU REGIME
E. R. Solano and R. D. Hazeltine Aug. 1993 11 p
(Contracts DE-FG05-88ER-53266; DE-FG05-89ER-53288)
(DE93-019825; DOE/ER-53266/45; FRCR-436) Avail: CASI HC A03/MF A01

Traditionally, neoclassical transport calculations ignore poloidal variation of the poloidal magnetic field. Near an X-point of the confining field of a diverted plasma, the poloidal field is small, causing guiding centers to linger at that poloidal position. We study how neoclassical transport is affected by this differential shaping. The problem is solved in general in the plateau regime, and a model poloidal flux function with an X-point is utilized as an analytic example to show that the plateau diffusion coefficient can change considerably (factor of 2 reduction). Ion poloidal rotation is proportional to the local value of B approaches pol, but otherwise it is not strongly affected by shaping. DOE

ASYMPTOTICS OF THE GLRT FOR THE DISORDER PROBLEM IN DIFFUSION PROCESSES
Fabien Campillo, Francois LeGland, and Yurii Kutoyants (Maine Univ., Le Mans, France.) Jul. 1992 26 p
(INRIA-RR-1735; ETN-93-94435) Avail: CASI HC A03/MF A01

The problem of detecting a change in the drift coefficient of a diffusion process (disorder problem), using the generalized likelihood ratio test (GLRT), is considered. Assuming that a change has occurred, the asymptotic behavior (consistency, asymptotic probability distribution) of the maximum likelihood estimate of the change time has already been investigated in the small noise asymptotics. This study addresses the asymptotics of the GLRT itself, i.e. the asymptotic behavior of both the probability of false alarm and the probability of miss detection. These probabilities are proven to go to zero with exponential rate, provided a simple detectability assumption is satisfied by the limiting deterministic system. The robustness of the GLRT with respect to model mis-specification, a very important property for practical implementation, is also investigated. Here, mis-specification means that some wrong expressions are used for either the drift coefficient (before change) or the change coefficient. Roughly the same behavior is obtained for the error probabilities, as in the correctly specified case, although the detectability assumption will include the requirement that the change to be detected is larger in some sense than the mis-specification error. HALF-INTEGRAL FLOWS IN A PLANAR GRAPH WITH FOUR HOLES
Alexander K. Karzanov Jun. 1992 53 p Sponsored by Mairie of Grenoble, France
(RR-894-M; ETN-93-94985) Avail: CASI HC A04/MF A01

Suppose that G = (VG, EG) is a planar graph embedded in the euclidean plane, that I, J, K, O are four of its faces (called holes in G), that s(sub 1),..., s(sub r), t(sub 1),..., t(sub r) are vertices of G such that each pair of the set s(sub i), t(sub i) belongs to the boundary of some I, J, K, O and that the graph (VG, EG union of the set of sets s(sub i), t(sub i),..., s(sub r), t(sub r)) is eulerian. It is proved that if the multi(commodity) flow problem in G with unit demands on the values of flows from s(sub i) to flows from s(sub i) to t(sub i), i = 1,...,r, has a solution then it has a half integral solution as well. In other words, there exist paths P(sub 1)(sup 1), P(sub 1)(sup 2), P(sub 2)(sup 2),..., P(sub r)(sup 1), P(sub r)(sup 2) in G such that each P(sub i)(sup j) connects s(sub i) and t(sub i), and each edge of G is covered at most twice by these paths. (It is known that in case of at most three holes there exist edge disjoint paths connecting s(sub i) and t(sub i), i = 1,...,r, provided that the corresponding multiflow problem has a solution, but this is, in general, false in case of four holes). ESA

SYSTEM FOR SOLVING BOOLEAN EQUATIONS USING OPTICAL LOOKUP TABLES Patent
Roy M. Reyes, inventor (to Navy) and Scott E. Spence, inventor (to Navy) 5 Oct. 1993 8 p Filed 2 Sep. 1992
(AD-D015962; US-Patent-5,251,052; US-Patent-Appl-SN-939229; US-Patent-Class-359-107) Avail: US Patent and Trademark Office

A reconfigurable digital optical lookup table for solving Boolean equations using in array of bistable optical devices is provided. A single light source is divided into a matrix of light beams using binary phase gratings and a lens system. This matrix of beams is modulated by a spatial light modulator symmetric self electro-optic effect device (S-SEED) according to the desired lookup table. The modulated light beams are used to set an S-SEED array with the lookup table. The rows and columns of the S-SEED array are then reset according to the inputs to the Boolean equation. Once all of the inputs have been processed, the S-SEED array will have only one member whose state has not been affected by the inputs, and the value of this S-SEED corresponds to the solution to the Boolean equation. The final result is output by using a matrix of equal intensity light beams and a mask to read out the state of one side of the S-SEEDs, and focusing the result onto a detector. DTIC

POLYNOMIAL INTERPOLATION OF REAL FUNCTIONS 1: INTERPOLATION IN AN INTERVAL Technical Note
Qi Chen (Sachs/Freeman Associates, Inc., Landover, MD.) and Ivo babuska Aug. 1993 31 p Sponsored in part by ARPA Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1030)
(AD-A272330; BN-1153) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper is the first in a series to analyze the accuracy of polynomial interpolation of functions and its dependence on the locations of the interpolation nodes. It surveys known results for polynomial interpolation in an interval. It also introduces the concept of the Minimal Interpolation Sets which are the 'optimal' interpolation sets. New results concerning the properties of the minimal sets as well as procedures for locating the minimal sets are presented. The table for the minimal sets in the L-norm is given. An adaptive scheme for determining the interpolation order is also presented. Examples show the efficacy of this approach. DTIC

During the three-year period of this project, we conducted research on the development, analysis, and application of serial and parallel adaptive computational strategies for solving transient and steady partial differential systems. Concentrating on high-order methods and adaptive approaches that combine mesh refinement and coarsening (h-refinement, order variation (p-refinement), and occasionally, mesh motion (r-refinement), we addressed problems in combustion, materials science, and compressible fluid mechanics. Special spatially-discrete finite element Galerkin methods were considered for the parallel and adaptive solution of hyperbolic conservation laws. Improved solution-limiting and error-estimation strategies increased the accuracy and efficiency of these methods which are being applied to two- and three-dimensional compressible flow problems. Adaptive techniques for dissipative systems are being applied to problems in the manufacture of ceramic composite media. DTIC

GRAPH MINORS: STRUCTURE THEORY AND ALGORITHMS
Robin Thomas 1993 7 p
(Contract N00014-93-1-0325)
(AD-A271851) Avail: CASI HC A02/MF A01

There have been significant developments in graph theory over the last decade that imply the existence of polynomial time algorithms for a large class of problems. These results, however, guarantee the existence of polynomial-time algorithms to solve various problems, but give no hint how to find one. Yet another drawback of these algorithms is that even though they are theoretically fast (O(n squared) or O(n cubed)), the constant hidden in the O notation is so enormous that it makes the algorithms impractical. The purpose of this project is to further develop this theory and obtain more theoretical results, apply these results to the design of at least theoretically efficient algorithms, and turn these theoretically efficient algorithms into practical ones. TWO-DIMENSIONAL NONLINEAR SCHRODINGER EQUATIONS AND THEIR PROPERTIES
D. J. Kaup and Ronald E. Kates Oct. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272184; INS-241) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper studies a general class of two-dimensional systems of the cubic nonlinear Schrodinger type (2DNLS), defined by i del(sub t) q + O(1)q = pq and O(2)p = O(3)(q*q), where each O(sub n) is equated to D(sub ij)(sup n) del(sub i) del(sub j), n = 1,2,3, is a linear, second-order, operator with constant coefficients. This class generalizes the Djordjevic-Redekopp (DR) system, which has previously been encountered in the context of water waves. Integrability is characterized simply in terms of covariant conditions on the O(n). We obtain all integrable cases, including the known cases Davey-Stewartson I and II as well as other known integrable cases. All other regimes are modulationally unstable and have projections satisfying the ordinary (1D) NLS with soliton solutions, though in all known cases these 1D solitons are unstable with respect to transverse perturbations. The self-focusing regime is characterized by the eigenvalues of the D(sub ij)(sup n): O(1) and O(2) must both be elliptic, and for that choice of variables for which D(sub ij)(sup 1) and D(sub ij)(sup 2) both have positive signature, D(subij)(sup 3) must have at least one negative eigenvalue. The self-focusing regime is distinct from the modulationally stable regime and also from the integrable regime, while the integrable cases may be modulationally stable or unstable. There are no soliton solutions known in those integrable cases that are modulationally stable, whereas those integrable cases in which 2D solitons are known correspond to the modulational instability regime. ASYMPTOTIC BEHAVIOR OF FOURIER TRANSFORM OF SURFACE MEASURES ON CONVEX AND RADIAL HYPERSURFACES Ph.D. Thesis [UEBER DAS ASYMPTOTISCHE VERHALTEN DER FOURIERTRANSFORMIERTEN VON OBERFLAECHENMASSEN AUF KONVEXEN UND RADIALEN HYPERFLAECHEN]
Helmut Schulz 1991 74 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-93790) Avail: CASI HC A04

Smooth and convex hypersurfaces S of finite type with Lebesgue surface measure d-theta and function u defined on S were considered. Estimations were given for the asymptotic behavior of: absolute value of (F bracket (modules of K) to the zth power u d theta bracket). K is the Gauss curvature and z a complex number with a non negative real part. The structure of S and K are simple so that singularities do not disturb the calculations, which are given with dependence on local geometric structures of S. ESA

TIGHT COMPARISON BOUNDS FOR THE STRING PREFIX-MATCHING PROBLEM
Dany Breslauer, Livio Colussi (Padua Univ., Italy.), and Laura Toniolo (Padua Univ., Italy.) Dec. 1992 10 p Sponsored in part by European Research Consortium for Informatics and Mathematics Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-CS-R9250; ETN-94-94730) Copyright Avail: CASI HC A02

The exact complexity of the string prefix matching problem in the deterministic sequential comparison model is studied. The bounds do not account for comparisons made in a pattern preprocessing step. The following results are presented: a family of linear time string prefix matching algorithms that make at most (((2m - 1)/m)n) comparisons; a tight lower bound (((2m - 1)/m)n) comparisons for any string prefix matching algorithm. The special case when the pattern and the text strings are the same string and all comparisons are accounted is also considered. This problem, called the string self prefix problem, is similar to the failure function that is computed in the pattern preprocessing of the Knuth Morris Pratt string matching algorithm and used in several other comparison efficient algorithms. By using the lower bound for the string prefix matching problem the following is shown: a lower bound of 2m - (2 times the square root of m) comparisons for the self-prefix problem. ESA

(ETN-93-93681) Avail: CASI HC A05

Mathematical models of excitation and propagation in nerves are developed, with reference to Hastings neurobiology models. Nonlinear differential difference equations, which described impulse transport in myelineated nerves, are examined. Two methods were used for modeling nonlinear terms: first, a nonlinear advanced differential-difference equation with three parameters in a model without recovery, and therefore an usual differential equation with five parameters in a model with recovery. Equations were discretized with finite differences and Sinc-Galerkin approximation method. A continuity process was developed for solving equations, which is based on the piecewise linear Newton method. Lemmas which guarantee existence and singleness of the solution are presented. The threshold values behavior for evaluating their conformity with physiology is discussed. ESA

ON THE CORE-STRUCTURE OF MINIMUM COST SPANNING TREE GAMES

Harry Aarts and Theo Driessen Oct. 1992 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(MEMO-1085; ETN-93-94125) Avail: CASI HC A03

It is a known result that Minimum Cost Spanning Tree (MCST) games possess nonempty cores and that some extreme points of the core can be deduced directly from the underlying network, that is, they can be described in terms of the costs of the edges (weight function) in the network. The determination of other extreme points of the core in this way is difficult because the precise connection between the core and the weight function is very complicated. Therefore there is still little known about the structure and the size of the core of MCST games. The connection between the core and the weight functions is studied. An adaptation of the weight function which does not change the core of the MCST game involved is introduced. For a special class of networks, this adaptation provides a useful description for the MCSTs in the various subnetworks. For this particular class, a second core invariant adaptation of the weight function is defined. The arising MCST games turn out to be exact games and the connection between the core and the (adapted) weights becomes much clearer. Many additional extreme points of the core can be deduced from the adapted network and a much better insight into the structure and the size of the core of these MCST games is obtained. The convexity of these games is investigated. ESA

(Rept-92-46; ETN-93-93856) Copyright Avail: CASI HC A03

The following is presented: let the set (S(sup lambda)(sub n)) denote a set of polynomials orthogonal with respect to the Sobolev inner product (f, g) = integral upper limit b, lower limit a, f(x)g(x) d(psi)(sub 0)(x) + lambda integral upper limit b, lower limit a, f'(x)g'(x)d(psi)(sub 1)(x) where (d(psi)(sub 0)), (d(psi)(sub 1)) is a coherent pair as introduced by Iserles et al. and lambda is greater than or equal to 0. Let (K(sub n)) and (H(sub n)) denote sets of polynomials orthogonal with respect to d(psi)(sub 0) respectively d(psi)(sub 1). If lambda is sufficiently large, then S(sup lambda)(sub n) has n different, real zeros interlacing with the zeros of K(sub n - 1) and with those of H(sub n - 1). If (d(psi)(sub 0), d(psi)(sub 1)) is a symmetrically coherent pair the situation is somewhat more complicated and S(sup lambda)(sub n) may have a pair of complex zeros. ESA

ADAPTIVE GRIDS FOR QUASILINEAR PARABOLIC SYSTEMS IN ONE SPACE DIMENSION Ph.D. Thesis [ADAPTIVE GITTER FUER QUASILINEARE PARABOLISCHE SYSTEME IN EINER RAUMDIMENSION]
Matthias Lappe 1990 95 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-93611) Avail: CASI HC A05

The problem of discretization for the numerical solution of partial differential equations is investigated with particular consideration to boundary conditions. Convergence issues with the method of lines were examined by considering Runge-Kutta processes of the semidiscrete problem. An algorithm for grid generation was achieved and applied to the linear heat conduction equation, the Burger equation, and a nonlinear system. The proposed method is particularly fitted for solving diffusion problem with Dirichlet boundary conditions. Existence and singleness of the solution were theoretically studied. ESA

HILBERT 90 FOR POLYNOMIAL MATRICES
Michiel Hazewinkel Dec. 1992 6 p
(CWI-AM-R9211; ETN-94-94711) Copyright Avail: CASI HC A02/MF A01

A generalization of the 'Hilbert 90' theorem is proved for unimodular polynomial matrices. Let K/k be a finite Galois extension with Galois group Gamma = Gal(K/k). Let GL(sub n)(K z(sub 1),..., z(sub m)) be the group of polynomial unimodular n by n matrices over K, that is the group of n by n matrices M with entries that are polynomials in m variables over K and such that det(M) is a member of K the set(0). The group Gamma acts on GL(sub n)(K z(sub 1),..., z(sub m)) by acting on the coefficients of the matrix elements. The main theorem given says that the corresponding first cohomology group is zero. FAST FOURIER TRANSFORMS FOR NONEQUISPACED DATA Ph.D. Thesis
Alok Dutt Aug. 1993 104 p
(Contract N00014-89-J-1527; NSF DMS-90-12751)
(AD-A272687) Avail: CASI HC A06/MF A01

Two groups of algorithms are presented generalizing the fast Fourier transform (FFT) to the case of non-integer frequencies and nonequispaced nodes on the interval (-pi, pi). These schemes are based on combinations of certain analytical considerations with the classical fast Fourier transform, and generalize both the forward and backward FFT's. The number of arithmetic operations required by each of the algorithms is proportional to N (dot) log N + N - log(1/epsilon), where epsilon is the desired precision of computations and N is the number of nodes. Several related algorithms are also presented, each of which utilizes a similar set of techniques from analysis and linear algebra. These include an efficient version of the Fast Multipole Method in one dimension and fast algorithms for the evaluation, integration, and differentiation of Lagrange polynomial interpolants. Several numerical examples are used to illustrate the efficiency of the approach, and to compare the performances of the two sets of nonuniform FFT algorithms. DTIC

CLASSICAL AND GENERALIZED SOLUTIONS OF TIME-DEPENDENT LINEAR DIFFERENTIAL ALGEBRAIC EQUATIONS Technical Report
Patrick J. Rabier and Werner C. Rheinboldt 15 Oct. 1993 40 p
(Contract N00014-90-J-1025; NSF CCR-92-03488)
(AD-A272834; ICMA-93-183) Avail: CASI HC A03/MF A01

A reduction procedure is developed for linear time-dependent differential algebraic equations (DAE's) that transforms their solutions into solutions of smaller systems of ordinary differential equations (ODE's). The procedure applies to classical as well as distribution solutions. In the case of analytic coefficients, the hypotheses required for the reduction not only are necessary for the validity of the existence and uniqueness results, but they even allow for the presence of singularities. Straightforward extensions including undetermined systems and systems with non-analytic coefficients are also discussed. DTIC

(TR-467) Avail: CASI HC A03/MF A01

Is there a single-valued NP function that, when given a satisfiable formula as input outputs a satisfying assignment? That is, can a nondeterministic function cull just one satisfying assignment from a possibly exponentially large collection of assignments? It is shown that if there is such a nondeterministic function, then the polynomial hierarchy collapses to its second level. As the existence of such a function is known to be equivalent to the statement 'every multivalued NP function has a single-valued NP refinement,' our result provides the strongest evidence yet that multivalued NP functions cannot be refined. Our result is proved via theorems of independent interest. We say that a set A is NPSV-selective (NPMV-selective) if there is a 2-ary partial function in NPSV (NPMV, respectively) that decides which of its inputs (if any) is 'more likely' to belong to A; this is a nondeterministic analog of the recursion-theoretic notion of the semi-recursive sets and the extant complexity-theoretic notion of P-selectivity. Our hierarchy collapse follows by combining the easy observation that every set in NP is NPMV-selective with either of the following two theorems that proved: (1) If A is a member of NP is NPSV-selective, then A is a member of (NP intersection coNP)/poly; and (2) If A is a member of NP is NPSV-selective, then A is Low(sub 2). To wit, either result implies that if every set in NP is NPSV-selective, then the polynomial hierarchy collapses to its second level, NP(sup NP).

ON A PROPOSED SYMBOLIC DYNAMICS FOR THE HENON MAP M.S. Thesis

Antonio P. Fontana Jun. 1993 169 p

(AD-A272514) Avail: CASI HC A08/MF A02

The utility of a computationally simple yet cryptologically robust rule for generating pseudorandom bitstreams cannot be overstated. In most applications we strive to detect and avoid chaotic behavior; here we embrace a particular chaotic discrete dynamical system to exploit its use as a driver for a pseudorandom number generator. The map from the Henon attractor to the binary domain (0,1) proposed by Forre/Heyman has been tested cryptologically and statistically with mixed results. In this thesis we mathematically evaluate this symbolic dynamics scheme and investigate more rigorously its utility as a pseudorandom number generator. Specifically, we demonstrate how the property of being one-to-one holds, but that the property of being onto does not.

THE SIXTH COPPER MOUNTAIN CONFERENCE ON MULTIGRID METHODS, PART 2

N. Duane Melson, ed., Steve F. McCormick, ed. (Colorado Univ., Denver.), and Thomas A. Manteuffel, ed. (Colorado Univ., Denver.) Washington Nov. 1993 342 p Workshop held in Copper Mountain, CO, 4-9 Apr. 1993; sponsored by NASA, AFOSR, DOE, and NSF

(RTOP 505-59-53-01)

(NASA-CP-3224-Pt-2; L-17275-Pt-2; NAS 1.55:3224-Pt-2) Avail: CASI HC A15/MF A03

The Sixth Copper Mountain Conference on Multigrid Methods was held on April 4-9, 1993, at Copper Mountain, Colorado. This book is a collection of many of the papers presented at the conference and so represents the conference proceedings. NASA Langley graciously provided printing of this document so that all of the papers could be presented in a single forum. Each paper was reviewed by a member of the conference organizing committee under the coordination of the editors. The multigrid discipline continues to expand and mature, as is evident from these proceedings. The vibrancy in this field is amply expressed in these important papers, and the collection clearly shows its rapid trend to further diversity and depth. For individual titles, see N94-21465 through N94-21487.

OPTIMAL RESOLUTION IN MAXIMUM ENTROPY IMAGE RECONSTRUCTION FROM PROJECTIONS WITH MULTIGRID ACCELERATION

Mark A. Limber, Thomas A. Manteuffel, Stephen F. McCormick, and David S. Sholl (Colorado Univ., Boulder.) *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 361-375 (For primary document see N94-21464 05-64)

Avail: CASI HC A03/MF A03

We consider the problem of image reconstruction from a finite number of projections over the space L(sup 1)(Omega), where Omega is a compact subset of the set of Real numbers (exp 2). We prove that, given a discretization of the projection space, the function that generates the correct projection data and maximizes the Boltzmann-Shannon entropy is piecewise constant on a certain discretization of Omega, which we call the 'optimal grid'. It is on this grid that one obtains the maximum resolution given the problem setup. The size of this grid grows very quickly as the number of projections and number of cells per projection grow, indicating fast computational methods are essential to make its use feasible. We use a Fenchel duality formulation of the problem to keep the number of variables small while still using the optimal discretization, and propose a multilevel scheme to improve convergence of a simple cyclic maximization scheme applied to the dual problem.

Avail: CASI HC A03/MF A03

We develop a new numerical approach to study the spatially evolving instability of the streamwise dominant flow in the presence of roughness elements. The difficulty in handling the flow over the boundary surface with general geometry is removed by using a new conservative form of the governing equations and an analytical mapping. The numerical scheme uses second-order backward Euler in time, fourth-order central differences in all three spatial directions, and boundary-fitted staggered grids. A three-dimensional channel with multiple two-dimensional-type roughness elements is employed as the test case. Fourier analysis is used to decompose different Fourier modes of the disturbance. The results show that surface roughness leads to transition at lower Reynolds number than for smooth channels.

We consider the numerical solution of the single-group, steady state, isotropic transport equation. An analysis by means of the moment equations shows that a discrete ordinate S(sub N) discretization in direction (angle) with a least squares finite element discretization in space does not behave properly in the diffusion limit. A scaling of the S(sub N) equations is

introduced so that the least squares discretization has the correct diffusion limit. For the resulting discrete system a full multigrid algorithm was developed. Author

We study the potential performance of multigrid algorithms running on massively parallel computers with the intent of discovering whether presently envisioned machines will provide an efficient platform for such algorithms. We consider the domain parallel version of the standard V cycle algorithm on model problems, discretized using finite difference techniques in two and three dimensions on block structured grids of size 10(exp 6) and 10(exp 9), respectively. Our models of parallel computation were developed to reflect the computing characteristics of the current generation of massively parallel multicomputers. These models are based on an interconnection network of 256 to 16,384 message passing, 'workstation size' processors executing in an SPMD mode. The first model accomplishes interprocessor communications through a multistage permutation network. The communication cost is a logarithmic function which is similar to the costs in a variety of different topologies. The second model allows single stage communication costs only. Both models were designed with information provided by machine developers and utilize implementation derived parameters. With the medium grain parallelism of the current generation and the high fixed cost of an interprocessor communication, our analysis suggests an efficient implementation requires the machine to support the efficient transmission of long messages, (up to 1000 words) or the high initiation cost of a communication must be significantly reduced through an alternative optimization technique. Furthermore, with variable length message capability, our analysis suggests the low diameter multistage networks provide little or no advantage over a simple single stage communications network. TIME-ACCURATE NAVIER-STOKES CALCULATIONS WITH MULTIGRID ACCELERATION
N. Duane Melson, Harold L. Atkins, and Mark D. Sanetrik (Analytical Services and Materials, Inc., Hampton, VA.) *In its* The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 423-437 (For primary document see N94-21464 05-64)
Avail: CASI HC A03/MF A03

A numerical scheme to solve the unsteady Navier-Stokes equations is described. The scheme is implemented by modifying the multigrid-multiblock version of the steady Navier-Stokes equations solver, TLNS3D. The scheme is fully implicit in time and uses TLNS3D to iteratively invert the equations at each physical time step. The design objective of the scheme is unconditional stability (at least for first- and second-order discretizations of the physical time derivatives). With unconditional stability, the choice of the time step is based on the physical phenomena to be resolved rather than limited by numerical stability which is especially important for high Reynolds number viscous flows, where the spatial variation of grid cell size can be as much as six orders of magnitude. An analysis of the iterative procedure and the implementation of this procedure in TLNS3D are discussed. Numerical results are presented to show both the capabilities of the scheme and its speed up relative to the use of global minimum time stepping. Reductions in computational times of an order of magnitude are demonstrated. Author

MGGHAT: ELLIPTIC PDE SOFTWARE WITH ADAPTIVE REFINEMENT, MULTIGRID AND HIGH ORDER FINITE ELEMENTS
William F. Mitchell *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 439-448 (For primary document see N94-21464 05-64)
Avail: CASI HC A02/MF A03

MGGHAT (MultiGrid Galerkin Hierarchical Adaptive Triangles) is a program for the solution of linear second order elliptic partial differential equations in two dimensional polygonal domains. This program is now available for public use. It is a finite element method with linear, quadratic or cubic elements over triangles. The adaptive refinement via newest vertex bisection and the multigrid iteration are both based on a hierarchical basis formulation. Visualization is available at run time through an X Window display, and a posteriori through output files that can be used as GNUPLOT input. In this paper, we describe the methods used by MGGHAT, define the problem domain for which it is appropriate, illustrate use of the program, show numerical and graphical examples, and explain how to obtain the software. Multigrid methods are good candidates for the resolution of the system arising in Numerical Fluid Dynamics. However, the question is to know if those algorithms which are efficient for the Poissan equation on structured meshes will still apply well to the Euler and Navier-Stokes equations on unstructured meshes. The study of elliptic problems leads us to define the conditions where a Full Multigrid strategy has O(N) complexity. The aim of this paper is to build a comparison between the elliptic theory and practical CFD problems. First, as an introduction, we will recall some basic definitions and theorems applied to a model problem. The goal of this section is to point out the different properties that we need to produce an FMG algorithm with O(N) complexity. Then, we will show how we can apply this theory to the fluid dynamics equations such as Euler and Navier-Stokes equations. At last, we present some results which are 2nd-order accurate and some explanations about the behavior of the FMG process. Author

In the present study, a scheme capable of solving very fast and robust complex nonlinear systems of equations is presented. The Block Adaptive Multigrid (BAM) solution method offers multigrid acceleration and adaptive grid refinement based on the prediction of the solution error. The proposed solution method was used with an implicit upwind Euler solver for the solution of complex transonic flows around airfoils. Very fast results were obtained (18-fold acceleration of the solution) using one fourth of the volumes of a global grid with the same solution accuracy for two test cases. Author

MULTIGRID SCHEMES FOR VISCOUS HYPERSONIC FLOWS **c02**
R. C. Swanson and R. Radespiel (Deutsche Forschungs- und Versuchsanstalt fuer Luft- und Raumfahrt, Brunswick, Germany.) *In its* The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 481-495 (For primary document see N94-21464 05-64)
Avail: CASI HC A03/MF A03

Several multigrid schemes are considered for the numerical computation of viscous hypersonic flows. For each scheme, the basic solution algorithm employs upwind spatial discretization with explicit multistage time stepping. Two-level versions of the various multigrid algorithms are applied to the two-dimensional advection equation, and Fourier analysis is used to determine their damping properties. The capabilities of the multigrid methods

are assessed by solving two different hypersonic flow problems. Some new multigrid schemes, based on semicoarsening strategies, are shown to be quite effective in relieving the stiffness caused by the high-aspect-ratio cells required to resolve high Reynolds number flows. These schemes exhibit good convergence rates for Reynolds numbers up to 200 x 10(exp 6). Author

LAYOUT OPTIMIZATION WITH ALGEBRAIC MULTIGRID METHODS

Hans Regler and Ulrich Ruede *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 497-511 Sponsored in part by Deutsche Forschungsgemeinschaft (DFG) (For primary document see N94-21464 05-64)

Avail: CASI HC A03/MF A03

Finding the optimal position for the individual cells (also called functional modules) on the chip surface is an important and difficult step in the design of integrated circuits. This paper deals with the problem of relative placement, that is the minimization of a quadratic functional with a large, sparse, positive definite system matrix. The basic optimization problem must be augmented by constraints to inhibit solutions where cells overlap. Besides classical iterative methods, based on conjugate gradients (CG), we show that algebraic multigrid methods (AMG) provide an interesting alternative. For moderately sized examples with about 10000 cells, AMG is already competitive with CG and is expected to be superior for larger problems. Besides the classical 'multiplicative' AMG algorithm where the levels are visited sequentially, we propose an 'additive' variant of AMG where levels may be treated in parallel and that is suitable as a preconditioner in the CG algorithm. Avail: CASI HC A03/MF A03

In this paper we describe a novel generalized SOR (successive overrelaxation) algorithm for accelerating the convergence of the dynamic iteration method known as waveform relaxation. A new convolution SOR algorithm is presented, along with a theorem for determining the optimal convolution SOR parameter. Both analytic and experimental results are given to demonstrate that the convergence of the convolution SOR algorithm is substantially faster than that of the more obvious frequency-independent waveform SOR algorithm. Finally, to demonstrate the general applicability of this new method, it is used to solve the differential-algebraic system generated by spatial discretization of the time-dependent semiconductor device equations. A MULTIGRID METHOD FOR STEADY EULER EQUATIONS ON UNSTRUCTURED ADAPTIVE GRIDS

Kris Riemslagh and Erik Dick *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 527-541 (For primary document see N94-21464 05-64)

Avail: CASI HC A03/MF A03

A flux-difference splitting type algorithm is formulated for the steady Euler equations on unstructured grids. The polynomial flux-difference splitting technique is used. A vertex-centered finite volume method is employed on a triangular mesh. The multigrid method is in defect-correction form. A relaxation procedure with a first order accurate inner iteration and a second-order correction performed only on the finest grid, is used. A multi-stage Jacobi relaxation method is employed as a smoother. Since the grid is unstructured a Jacobi type is chosen. The multi-staging is necessary to provide sufficient smoothing properties. The domain is discretized using a Delaunay triangular mesh generator. Three grids with more or less uniform distribution of nodes but with different resolution are generated by successive refinement of the coarsest grid. Nodes of coarser grids appear in the finer grids. The multigrid method is started on these grids. As soon as the residual drops below a threshold value, an adaptive refinement is started. The solution on the adaptively refined grid is accelerated by a multigrid procedure. The coarser multigrid grids are generated by successive coarsening through point removement. The adaption cycle is repeated a few times. Results are given for the transonic flow over a NACA-0012 airfoil. Author

Two-level domain decomposition methods are developed for a simple nonconforming approximation of second order elliptic problems. A bound is established for the condition number of these iterative methods, which grows only logarithmically with the number of degrees of freedom in each subregion. This bound holds for two and three dimensions and is independent of jumps in the value of the coefficients. Author

AN AUTOMATIC MULTIGRID METHOD FOR THE SOLUTION OF SPARSE LINEAR SYSTEMS

Yair Shapira, Moshe Israeli, and Avram Sidi *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 567-582 (For primary document see N94-21464 05-64)

Avail: CASI HC A03/MF A03

An automatic version of the multigrid method for the solution of linear systems arising from the discretization of elliptic PDE's is presented. This version is based on the structure of the algebraic system solely, and does not use the original partial differential operator. Numerical experiments show that for the Poisson equation the rate of convergence of our method is equal to that of classical multigrid methods. Moreover, the method is robust in the sense that its high rate of convergence is conserved for other classes of problems: non-symmetric, hyperbolic (even with closed characteristics) and problems on non-uniform grids. No double discretization or special treatment of sub-domains (e.g. boundaries) is needed. When supplemented with a vector extrapolation method, high rates of convergence are achieved also for anisotropic and discontinuous problems and also for indefinite Helmholtz equations. A new double discretization strategy is proposed for finite and spectral element schemes and is found better than known strategies. Author

Avail: CASI HC A02/MF A03

In this article, we discuss a non-variational V-cycle multigrid algorithm based on the cell-centered finite difference scheme for solving a second-order elliptic problem with discontinuous coefficients. Due to the poor approximation property of piecewise constant spaces and the non-variational nature of our scheme, one step of symmetric linear smoothing in our V-cycle multigrid scheme may fail to be a contraction. Again, because of the simple structure of the piecewise constant spaces, prolongation and restriction are trivial; we save significant computation time with very promising computational results. Avail: CASI HC A03/MF A03

We present a formulation of the shallow water equations that emphasizes the conservation of potential vorticity. A locally conservative semi-Lagrangian time-stepping scheme is developed, which leads to a system of three coupled PDE's to be solved at each time level. We describe a smoothing analysis of these equations, on which an effective multigrid solver is constructed. Some results from applying this solver to the static version of these equations are presented. Author

MULTIGRID SOLUTION OF THE NAVIER-STOKES EQUATIONS ON HIGHLY STRETCHED GRIDS WITH DEFECT CORRECTION **c34**
Peter M. Sockol *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 605-619 (For primary document see N94-21464 05-64)
Avail: CASI HC A03/MF A03

Relaxation-based multigrid solvers for the steady incompressible Navier-Stokes equations are examined to determine their computational speed and robustness. Four relaxation methods with a common discretization have been used as smoothers in a single tailored multigrid procedure. The equations are discretized on a staggered grid with first order upwind used for convection in the relaxation process on all grids and defect correction to second order central on the fine grid introduced once per multigrid cycle. A fixed W(1,1) cycle with full weighting of residuals is used in the FAS multigrid process. The resulting solvers have been applied to three 2D flow problems, over a range of Reynolds numbers, on both uniform and highly stretched grids. In all cases the L(sub 2) norm of the velocity changes is reduced to 10(exp -6) in a few 10's of fine grid sweeps. The results from this study are used to draw conclusions on the strengths and weaknesses of the individual relaxation schemes as well as those of the overall multigrid procedure when used as a solver on highly stretched grids. THE MULTIGRID PRECONDITIONED CONJUGATE GRADIENT METHOD
Osamu Tatebe *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 621-634 (For primary document see N94-21464 05-64)
Avail: CASI HC A03/MF A03

A multigrid preconditioned conjugate gradient method (MGCG method), which uses the multigrid method as a preconditioner of the PCG method, is proposed. The multigrid method has inherent high parallelism and improves convergence of long wavelength components, which is important in iterative methods. By using this method as a preconditioner of the PCG method, an efficient method with high parallelism and fast convergence is obtained. First, it is considered a necessary condition of the multigrid preconditioner in order to satisfy requirements of a preconditioner of the PCG method. Next numerical experiments show a behavior of the MGCG method and that the MGCG method is superior to both the ICCG method and the multigrid method in point of fast convergence and high parallelism. This fast convergence is understood in terms of the eigenvalue analysis of the preconditioned matrix. From this observation of the multigrid preconditioner, it is realized that the MGCG method converges in very few iterations and the multigrid preconditioner is a desirable preconditioner of the conjugate gradient method. The convergence rate of standard multigrid algorithms degenerates on problems with stretched grids or anisotropic operators. The usual cure for this is the use of line or plane relaxation. However, multigrid algorithms based on line and plane relaxation have limited and awkward parallelism and are quite difficult to map effectively to highly parallel architectures. Newer multigrid algorithms that overcome anisotropy through the use of multiple coarse grids rather than relaxation are better suited to massively parallel architectures because they require only simple point-relaxation smoothers. In this paper, we look at the parallel implementation of a V-cycle multiple semicoarsened grid (MSG) algorithm on distributed-memory architectures such as the Intel iPSC/860 and Paragon computers. The MSG algorithms provide two levels of parallelism: parallelism within the relaxation or interpolation on each grid and across the grids on each multigrid level. Both levels of parallelism must be exploited to map these algorithms effectively to parallel architectures. This paper describes a mapping of an MSG algorithm to distributed-memory architectures that demonstrates how both levels of parallelism can be exploited. The result is a robust and effective multigrid algorithm for distributed-memory machines. Author

In this work the compressible Euler equations are solved using finite volume techniques on unstructured grids. The spatial discretization employs a central difference approximation augmented by dissipative terms. Temporal discretization is done using a multistage Runge-Kutta scheme. A multigrid technique is used to accelerate convergence to steady state. The coarse grids are derived directly from the given fine grid through agglomeration of the control volumes. This agglomeration is accomplished by using a greedy-type algorithm and is done in such a way that the load, which is proportional to the number of edges, goes down by nearly a factor of 4 when moving from a fine to a coarse grid. The agglomeration algorithm has been implemented and the grids have been tested in a multigrid code. An area-weighted restriction is applied when moving from fine to coarse grids while a trivial injection is used for prolongation. Across a range of geometries and flows, it is shown that the agglomeration multigrid scheme compares very favorably with an unstructured multigrid algorithm that makes use of independent coarse meshes, both in terms of convergence and elapsed times. MULTIGRID PROPERTIES OF UPWIND-BIASED DATA RECONSTRUCTIONS **c34**
Gary P. Warren and Thomas W. Roberts *In its* The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 663-677 (For primary document see N94-21464 05-64)
Avail: CASI HC A03/MF A03

The multigrid properties of two data reconstruction methods used for achieving second-order spatial accuracy when solving the two-dimensional Euler equations are examined. The data reconstruction methods are used with an implicit upwind algorithm which uses linearized backward-Euler time-differencing. The solution of the resulting linear system is performed by an iterative procedure. In the present study only regular quadrilateral grids are considered, so a red-black Gauss-Seidel iteration is used. Although the Jacobian is approximated by first-order upwind extrapolation, two alternative data reconstruction techniques for the flux integral that yield higher-order spatial accuracy at steady state are examined. The first method, probably most popular for structured quadrilateral grids, is based on estimating the cell gradients using one-dimensional reconstruction along curvilinear coordinates. The second method is based on Green's theorem. Analysis and numerical results for the two dimensional Euler equations show that data reconstruction based on Green's theorem has superior multigrid properties as compared to the one-dimensional data reconstruction method. A single grid local mode analysis is used to predict the smoothing properties of numerical schemes for solving the Navier-Stokes equations with factorization based on Stone's Strongly Implicit Method. Four difference approximations for the convection terms are considered, namely, hybrid, central, second-order upwind, and third-order upwind. Smoothing factors from the analysis are compared with practical convergence factors in a multigrid method for flow over a backward facing step and it is found that the local mode analysis correctly predicts the effects of Reynolds number and higher-order schemes. NUMERICAL STUDY OF A MULTIGRID METHOD WITH FOUR SMOOTHING METHODS FOR THE INCOMPRESSIBLE NAVIER-STOKES EQUATIONS IN GENERAL COORDINATES c34
S. Zeng and P. Wesseling *In* NASA. Langley Research Center, The Sixth Copper Mountain Conference on Multigrid Methods, Part 2 Nov. 1993 p 691-708 (For primary document see N94-21464 05-64)
Avail: CASI HC A03/MF A03

The performance of a linear multigrid method using four smoothing methods, called SCGS (Symmetrical Coupled GauBeta-Seidel), CLGS (Collective Line GauBeta-Seidel), SILU (Scalar ILU), and CILU (Collective ILU), is investigated for the incompressible Navier-Stokes equations in general coordinates, in association with Galerkin coarse grid approximation. Robustness and efficiency are measured and compared by application to test problems. The numerical results show that CILU is the most robust, SILU the least, with CLGS and SCGS in between. CLGS is the best in efficiency, SCGS and CILU follow, and SILU is the worst.

TOWARD A NEW METHOD OF DECODING ALGEBRAIC CODES USING GROEBNER BASES Final Report, Oct. 1991 - Sep. 1992
A. B. Cooper, III Oct. 1993 23 p
(AD-A273089; ARL-TR-293) Avail: CASI HC A03/MF A01

A binary BCH error control code is a vector subspace of binary N-tuples. Algebraically, the code is generated by a polynomial having binary coefficients and roots in GF(2(sup m)). It is decoded by computing a set of syndrome equations which are multivariate polynomials over GF(2(sup m)) and which exhibit a certain symmetry. If the number of transmission errors in a received word does not exceed a bound t for the code, the roots of the syndromes are the locations, in the received word, of those errors. These multivariate polynomials are taken as the basis for an ideal in the ring of polynomials in t variables over GF(2(sup m)). A celebrated algorithm by Buchberger produces a reduced Groebner basis of that ideal. It turns out that since the common roots of all the polynomials in the ideal are a set of isolated points, this reduced Groebner basis is in triangular form, and the univariate polynomial in that basis is the well known BCH error locator polynomial, the roots of which specify the error locations. Decoding is algorithmically complete when this polynomial is known.

RATIONAL TRIGONOMETRIC APPROXIMATIONS USING FOURIER SERIES PARTIAL SUMS Final Report
James F. Geer (State Univ. of New York, Binghamton.) Sep. 1993 34 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191535; NAS 1.26:191535; ICASE-93-68) Avail: CASI HC A03/MF A01

A class of approximations (S(sub N,M)) to a periodic function f which uses the ideas of Pade, or rational function, approximations based on the Fourier series representation of f, rather than on the Taylor series representation of f, is introduced and studied. Each approximation S(sub N,M) is the quotient of a trigonometric polynomial of degree N and a trigonometric polynomial of degree M. The coefficients in these polynomials are determined by requiring that an appropriate number of the Fourier coefficients of S(sub N,M) agree with those of f. Explicit expressions are derived for these coefficients in terms of the Fourier coefficients of f. It is proven that these 'Fourier-Pade' approximations converge point-wise to (f(x(exp +))+f(x(exp -)))/2 more rapidly (in some cases by a factor of 1/k(exp 2M)) than the Fourier series partial sums on which they are based. The approximations are illustrated by several examples and an application to the solution of an initial, boundary value problem for the simple heat equation is presented. Author

COMPARING QUASI-NEWTON METHODS FOR SOLVING SPARSE INTERFACE PROBLEMS
C.-H. Lai Jan. 1993 13 p Sponsored by European Research Consortium for Informatics and Mathematics
(CWI-NM-R9303; ETN-94-94705) Copyright Avail: CASI HC A03/MF A01

Quasi Newton methods for interface problems which arise from domain decomposition methods are examined. These interface problems are usually sparse systems of linear or nonlinear equations. Particular interest is the application of the methods to systems of linear equations where the Jacobian matrices cannot be calculated or it is not wished to calculate them. The suitability of implementing these algorithms on coarse grained parallel computers is examined. ESA

ORDER OF ACCURACY OF QUICK AND RELATED CONVECTION-DIFFUSION SCHEMES
B. P. Leonard Nov. 1993 32 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106402; ICOMP-93-47; E-8236; NAS 1.15:106402) Avail: CASI HC A03/MF A01

This report attempts to correct some misunderstandings that have appeared in the literature concerning the order of accuracy of the QUICK scheme for steady-state convective modeling. Other related convection-diffusion schemes are also considered. The original one-dimensional QUICK scheme written in terms of nodal-point values of the convected variable (with a 1/8-factor multiplying the 'curvature' term) is indeed a third-order representation of the finite volume formulation of the convection operator average across the control volume, written naturally in flux-difference form. An alternative single-point upwind difference scheme (SPUDS) using node values (with a 1/6-factor) is a third-order representation of the finite difference single-point formulation; this can be written in a pseudo-flux difference form. These are both third-order convection schemes; however, the QUICK finite volume convection operator is 33 percent more accurate than the single-point implementation of SPUDS. Another finite volume scheme, writing convective fluxes in terms of cell-average values, requires a 1/6-factor for third-order accuracy. For completeness, one can also write a single-point formulation of the convective derivative in terms of cell averages, and then express this in pseudo-flux difference form; for third-order accuracy, this requires a curvature factor of 5/24. Diffusion operators are also considered in both single-point and finite volume formulations. Finite volume formulations are found to be significantly more accurate. For example, classical second-order central differencing for the second derivative is exactly twice as accurate in a finite volume formulation as it is in single-point. Author (revised)

OPERATIONAL EQUATIONS FOR THE FIVE-POINT RECTANGLE
G. L. Silver 15 Sep. 1993 36 p
(Contract DE-AC04-88DP-43495)
(DE94-000366; MLM-3787) Avail: CASI HC A03/MF A01

Two operational polynomials are demonstrated for the four-point rectangle with center point. The equations are exact on the points and the surfaces they describe ordinarily fit known monotonic surfaces better than the standard five-point equation, as judged by the L(sub 2) norm test. Equations for fitting the five-point rectangle by sines and cosines are presented. DOE

THE ACCURACY-THROUGH-ORDER AND THE EQUIVALENCE PROPERTIES IN THE ALGEBRAIC APPROXIMANT
G. A. Baker, Jr. 1993 7 p Presented at the Nonlinear Numerical Methods and Rational Approximation, Antwerp, Belgium, 6-10 Sep. 1993
(Contract W-7405-eng-36)
(DE93-040188; LA-UR-93-3072; CONF-9309227-1) Avail: CASI HC A02/MF A01

In addition to the accuracy through order requirement that the defining polynomials not all be divisible by z, as required for Pade and integral approximants, there is the further problem of deficiency as pointed out by McInnes. The author proves a finite bound on the deficiency and also proves the accuracy through order property for algebraic approximants. In addition he proves the equivalence property for algebraic approximants. DOE

THE QUANTUM STRUCTURE OF MATTER GRAND CHALLENGE PROJECT: LARGE-SCALE 3-D SOLUTIONS IN RELATIVISTIC QUANTUM DYNAMICS
J. C. Wells, V. E. Oberacker, A. S. Umar, C. Bottcher, M. R. Strayer, J. Drake, and R. Flanery 1993 11 p Presented at the Supercomputing Conference on High Performance Computing and Communications, Portland, OR, 15-19 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000328; CONF-931115-12) Avail: CASI HC A03/MF A01

We describe the numerical methods used to solve the time-dependent Dirac equation on a three-dimensional Cartesian lattice. Efficient algorithms are required for computationally intensive studies of nonperturbative relativistic quantum dynamics. Discretization is achieved through the lattice basis-spline collocation method, in which quantum-state vectors and coordinate-space operators are expressed in terms of basis-spline functions on a spatial lattice. All numerical procedures reduce to a series of matrix-vector operations which we perform on the Intel iPSC/860 hypercube, making full use of parallelism. We discuss our solutions to the problems of limited node memory and node-to-node communication overhead inherent in using distributed-memory, multiple-instruction, multiple-data stream parallel computers. A SHARP UPPER BOUND FOR DEPARTURE FROM NORMALITY
S. L. Lee Aug. 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE93-040457; ORNL/TM-12426) Avail: CASI HC A03

The departure from normality of a matrix is a real scalar that is impractical to compute if a matrix is large and its eigenvalues are unknown. A simple formula is presented for computing an upper bound for departure from normality in the Frobenius norm. This new upper bound is cheaper to compute than the upper bound derived by Henrici. Moreover, the new bound is sharp for Hermitian matrices, skew-Hermitian matrices, and, in general, any matrix with eigenvalues that are horizontally or vertically aligned in the complex plane. In terms of applications, the new bound can be used in computing bounds for the spectral norm of matrix functions or bounds for the sensitivity of eigenvalues to matrix perturbations. DOE

THE DESIGN OF LINEAR ALGEBRA LIBRARIES FOR HIGH PERFORMANCE COMPUTERS
J. J. Dongarra and D. W. Walker Aug. 1993 56 p
(Contract DE-AC05-84OR-21400)
(DE93-040458; ORNL/TM-12404) Avail: CASI HC A04/MF A01

This paper discusses the design of linear algebra libraries for high performance computers. Particular emphasis is placed on the development of scalable algorithms for MIMD distributed memory concurrent computers. A brief description of the EISPACK, LINPACK, and LAPACK libraries is given, followed by an outline of ScaLAPACK, which is a distributed memory version of LAPACK currently under development. The importance of block-partitioned algorithms in reducing the frequency of data movement between different levels of hierarchical memory is stressed. The use of such algorithms helps reduce the message startup costs on distributed memory concurrent computers. Other key ideas in our approach are the use of distributed versions of the Level 3 Basic Linear Algebra Subprograms (BLAS) as computational building blocks, and the use of Basic Linear Algebra Communication Subprograms (BLACS) as communication building blocks. Together the distributed BLAS and the BLACS can be used to construct higher-level algorithms and hide many details of the parallelism from the application developer. The block-cyclic data distribution is described and adopted as a good way of distributing block-partitioned matrices. Block-partitioned versions of the Cholesky and LU factorizations are presented, and optimization issues associated with the implementation of the LU factorization algorithm on distributed memory concurrent computers are discussed, together with its performance on the Intel Delta system. Finally, approaches to the design of library interfaces are reviewed. DOE

A FINITE ELEMENT FORMULATION AND ADAPTIVE SOLUTION APPROACH FOR LARGE-SCALE THERMOMECHANICAL PROBLEMS WITH COMPLEX CONTACT CONDITIONS
B. E. Engelmann, R. G. Whirley, and P. J. Raboin 31 Mar. 1993 14 p Presented at the 8th International Conference on Numerical Methods in Laminar and Turbulent Flow, Swansea, United Kingdom, 18-23 Jul. 1993
(Contract W-7405-eng-48)
(DE93-019605; UCRL-JC-112596; CONF-930785-3) Avail: CASI HC A03/MF A01

Traditional thermal stress analysis is based on an uncoupled approach in which the thermal problem is solved on a fixed geometry, and the resulting temperatures are then used to load a mechanical problem. In contrast, a fully coupled thermomechanical analysis solves the thermal problem on the deforming geometry and incorporates thermal loads into the mechanical problem. Thermal contact, in which heat flow paths depend on the mechanical deformations of adjacent surfaces, is a major component of many fully coupled thermomechanical analyses. This paper describes the development of a Lagrangian finite element thermomechanical contact methodology. The paper focuses on the formulation and implementation of thermal contact in two dimensions. The proposed approach accommodates arbitrarily large relative motions of contact surfaces, fully unstructured meshes, pressure-dependent contact resistance, conduction across small gaps, and approximate models for convection and radiation. The proposed thermal contact formulation has been implemented in the Lawrence Livermore National Laboratory public code PALM2D and has been used to solve a diverse set of thermomechanical problems. Examples frustrating the performance of this code on large deformation thermomechanical problems are presented and discussed. DOE

TIME-LAPLACE-TRANSFORM-DOMAIN ANALYSIS OF WAVE PROPAGATION IN PLANAR WAVEGUIDES
K. F. I. Haak 1992 56 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-215226; ET/EM-1992-28) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The time-Laplace longitudinal-wavenumber analysis of the wave propagation along closed and open, possibly lossy, planar waveguiding structures leads to remarkable conclusions. For the closed waveguides, all of the solutions pertaining to the discrete infinite spectrum correspond to causal propagating guided waves. For the open waveguides however, a discrete spectrum that corresponds to a set of causal solutions does not exist. This implies that in an open electromagnetic waveguide there is no time-Laplace-domain equivalent of the frequency-domain concept of discrete propagating modes. NTIS

NON COMMUTATIVE GEOMETRY AND PHYSICS
A. Connes Jun. 1993 142 p
(PB93-215499; IHES/M-93/32) Avail: CASI HC A07/MF A02

The set of lectures is an introduction to non-commutative geometry. The general purpose of non-commutative geometry is to adapt the traditional tools of geometry such as measure theory, topology, differential calculus and Riemannian geometry to spaces X which can no longer be comprehended as point sets because of their intrinisically quantum nature. The purpose of this course however, is not only to provide an introduction to non-commutative geometry, but also to survey the interplay between a selection of the latest developments with theoretical physics. In particular, one shall see how experimental physics leads us to accept not only the quantization of phase space, but also that of the Brillouin zone in solid state physics and even of space-time itself. Contents: (1) The involutive algebra of coordinates on a quantum space X; (2) Measure theory and representations; (3) C*-algebras and topology; (4) Vector bundles and cyclic cohomology; (5) The quantized calculus; (6) The metric aspect and classical matter fields; (7) The notion of manifold in non-commutative geometry; (8) Geometric interpretation of the standard model. MODULAR INTERVAL SPACES
H. J. Bandelt (Hamburg Univ., Germany.), M. VanDeVel, and E. Verheul Nov. 1992 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-220663; WS-404) Avail: CASI HC A03/MF A01

Modular interval spaces represent a common generalization of Banach spaces of type L(sub 1)(mu) or B(X), of hyperconvex metric spaces, modular lattices, modular graphs, and median algebras. It turns out that several types of structures are susceptible for a notion capturing essential features of modularity in lattices, e.g. semilattices, multilattices, metric spaces, ternary algebras, and graphs. There is no perfect correspondence between modular structures of various types unless the existence of a neutral point is imposed. Modular structures with neutral points embed in modular lattices. Particular modular interval spaces (e.g. median spaces, or more generally, modular spaces in which intervals are lattices) can be characterized by forbidden subspaces. NTIS

SEMI-STABILITY AND HEIGHTS OF CYCLES
J. B. Bost Jun. 1993 38 p
(PB93-215507; IHES/M-93/31) Avail: CASI HC A03/MF A01

The following, (pi): P(E) yields C, is a projective bundle over a projective curve. X is included in P(E) as a subvariety of dimension d flat over C. Extending the earlier work of Mumford and Vieweg, Cornalba and Harris proved that, if the Hilbert point of the generic fiber X(sub eta) included in P(E(Sub eta)) of (pi): X yields C is semi-stable in the sense of geometric invariant theory, then the intersection number C(sub 1)O(sub E)(1)(sup d)(small bullet)(in brackets: X) satisfies a non-trivial lower bound in terms of the degree deg E of the vector bundle E on C. In the paper the author proves an arithmetic analogue of this inequality and gives some applications. NTIS

HYPERSINGULAR INTEGRALS AT A CORNER
L. J. Gray and L. L. Manne 25 Mar. 1993 17 p Presented at the 15th Boundary Element Methods Conference, Worcester, MA, 10-12 Aug. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000340; CONF-9308176-1) Avail: CASI HC A03/MF A01

For a smooth boundary, hypersingular integrals can be defined as a limit from the interior, the approach direction being taken, for convenience, normal to the surface. At a boundary corner, the limit process, with a necessarily non-normal approach direction, provides a valid definition of the hypersingular equation, as long as the direction is employed for all integrations. The terms which are potentially singular in the limit are shown to cancel, provided the function approximations at the corner are consistent. The analytical formulas for the singular integrals are more complicated than for a smooth surface, but are easily obtained using symbolic computation. These techniques have been employed to accurately solve the 'L-shaped domain' potential problem considered by Jaswon and Symm. DOE

ASYMPTOTIC ANALYSIS. WORKING NOTE NO. 2, APPROXIMATION OF INTEGRALS
M. Garbey (Lyon-1 Univ., Villeurbanne, France.) and H. G. Kaper Jul. 1993 17 p
(Contract W-31-109-eng-38)
(DE94-000433; ANL/MCS-TM-180) Avail: CASI HC A03/MF A01

In this note we discuss the approximation of integrals that depend on a parameter. The basic tool is simple, namely, integration by parts. Of course, the power of the tool is evidenced in applications. The applications are numerous: Laplace integrals; generalized Laplace integrals; Fourier integrals; and Stokes' method of stationary phase for generalized Fourier integrals. These results illustrate beautifully Hardy's concept of applications of mathematics, that is, 'certain regions of mathematical theory in which the notation and the ideas of the method of integration by parts may be used systematically with a great gain in clearness and simplicity.' The notation differs slightly from Working Note No. 1, for reasons that are mainly historical. The asymptotic analysis of integrals originated in complex analysis, where the (real or complex) parameter, usually denoted by x, is usually introduced in such a way that the interesting behavior of the integrals occurs when x (yields) (infinity) in some sector of the complex plane. As there is nothing sacred about notation, and historical precedent is as good a guide as any, we follow convention and denote the parameter by x, focusing on the behavior of integrals as x (yields) (infinity) along the real axis or, if x is complex, in some sector of the complex plane. The connection with the notation of Working Note No. 1 is readily established by identifying the small parameter epsilon with 1/the absolute value of x. DOE

ASYMPTOTIC ANALYSIS: BASIC CONCEPTS AND DEFINITIONS Working Note No. 1
M. Garbey (Lyon-1 Univ., Villeurbanne, France.) and H. G. Kaper Jul. 1993 16 p
(Contract W-31-109-eng-38)
(DE94-001000; ANL/MCS-TM-179) Avail: CASI HC A03/MF A01

We introduce the basic concepts of asymptotic analysis. After some comments of historical interest, we begin by defining the order relations O, o, and O(sup (number sign)), which enable us to compare the asymptotic behavior of functions of a small positive parameter (epsilon) as (epsilon) (down arrow) 0. Next, we introduce order functions, asymptotic sequences of order functions and more general gauge sets of order functions and define the concepts of an asymptotic approximation and an asymptotic expansion with respect to a given gauge set. This string of definitions culminates in the introduction of the concept of a regular asymptotic expansion, also known as a Poincare expansion, of a function f : (0, epsilon(sub o)) yields X, where X is a normed vector space of functions defined on a domain D is a member of the set R(sup N). We conclude the note with the asymptotic analysis of an initial value problem whose solution is obtained in the form of a regular asymptotic expansion. DOE

Approaches like finite differences with common random numbers, infinitesimal perturbation analysis, and the likelihood ratio method, have recently drawn attention as ways of estimating the gradient of a performance measure with respect to continuous parameters in dynamic stochastic systems. In this paper, we study the use of such estimators in stochastic approximation algorithms, to perform so-called 'single-run optimizations' of steady-state systems. Under mild conditions, for an objective function that involves the mean system time in a G1/G/1 queue, we prove that many variants of these algorithms converge to the minimizer. In most cases, however, the simulation length must be increased from iteration to iteration; otherwise the algorithm may converge to the wrong value. One exception is a particular implementation of infinitesimal perturbation analysis, for which the single-run optimization converges to the optimum even with a fixed (and small) number of ends of service per iteration. As a by-product of our convergence proofs, we obtain some properties of the derivative estimators that could be of independent interest. DTIC

Avail: Issuing Activity (National Technical Information Service (NTIS))

The paper meets the application of Scott domains to nominalization and explains its problem of predication. It claims that it is not possible to find a solution to such a problem within semantic domains without logic. Frege structures are more conclusive than a solution to domain equations and can be used as models for nominalization. Hence, it develops a type theory based on Frege structures and uses it as a theory of nominalization. NTIS

(AD-A270887; AI-TR-1398) Avail: CASI HC A09

To be practical, recognition systems must deal with uncertainty. Positions of image features in scenes vary. Features sometimes fail to appear because of unfavorable illumination. In this work, methods of statistical inference are combined with empirical models of uncertainty in order to evaluate and refine hypotheses about the occurrence of a known object in a scene.

Probabilistic models are used to characterize image features and their correspondences. A statistical approach is taken for the acquisition of object models from observations in images: mean edge images are used to capture object features that are reasonably stable with respect to variations in illumination. DETERMINATION OF THE OPTIMAL STOCHASTIC UPPER BOUND OF A MARKOVIAN GENERATOR
Marc Tremolieres, Jean-Marc Vincent, and Brigitte Plateau Nov. 1992 18 p
(RR-906-I; ETN-93-94995) Avail: CASI HC A03/MF A01

An algorithm that computes a monotone Markovian infinitesimal generator that is stochastically greater than a given stochastic matrix A is proposed. This problem arises in the bounding of the marginal distributions of a continuous time Markov chain defined on a product space. The algorithm uses only basic algebraic operations, and it is shown that the matrix B constructed is optimal: any other monotone stochastic matrix C greater than A is also greater than B. Means of computing lower bounds are explained. ESA

THE COMBINATORICS OF RECONSTRUCTING EVOLUTIONARY TREES
L. A. Szekely (Eoetvoes Lorand Univ., Budapest, Hungary.), P. L. Erdoes (Hungarian Academy of Sciences, Budapest.), and M. A. Steel (Canterbury Univ., Christchurch, New Zealand.) Dec. 1992 19 p Sponsored in part by Alexander von Humboldt Stiftung, Germany
(Contract N00014-91-J-1385)
(CWI-BS-R9233; ETN-94-94722) Copyright Avail: CASI HC A03/MF A01

Results and problems from the reconstruction Theory of evolutionary trees, which involve enumeration and inversion, are surveyed. Every bit of the aligned DNA (deoxyribonucleic acid) sequence is assumed to be one of four nucleotides, that is, insertions and deletions of nucleotides are neglected. A Fourier inverse pair depending on trees and Abelian groups is described, and Kimura's models of molecular evolution are set into this context. The spectral analysis/closest tree method is outlined. The construction of a complete set of invariants for Cavender's model and Kimura's three parameter model is described. Remarks on algorithmic and philosophical aspects are given. ESA

SPECIFICATION AND GENERATION OF MARKOV REWARD MODELS
Boudewijn R. Haverkort and Kishor S. Trivedi (Duke Univ., Durham, NC.) 10 Sep. 1992 38 p Sponsored in part by NSWC Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant NSF CCR-91-08114)
(Memo-INF-92-60; TIOS-92-27; ETN-93-93838) Copyright Avail: CASI HC A03

A study on Markov Reward Models (MRM's) with emphasis on specification techniques is presented. This emphasis is done in an application independent way. Seven classes of specification techniques are distinguished: stochastic Petri nets, queueing networks, fault trees, production rule systems, communicating processes, specialized languages and hybrid techniques. For these classes, the main principles are discussed, examples are given, and software environments (tools) that support the use of these techniques are discussed. Earlier overviews were either only from a particular application area point of view or from a particular specification technique. The mapping of the high level specifications to the underlying MRM's, that is, the generation of the underlying MRM from the high level specification, is also addressed. Indications of important future research areas are given. ESA

LINEAR PROGRAMMING FOR STANDARD AND NONSTANDARD MARKOVIAN CONTROL PROBLEMS. A SURVEY
L. C. M. Kallenberg 1993 66 p See also PB93-191930 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-191948; TW-92-12) Avail: Issuing Activity (National Technical Information Service (NTIS))

An overview is given of linear programming methods for solving standard and nonstandard Markovian control problems. Standard problems are problems with the usual criteria such as expected total (discounted) rewards and average expected rewards. Also discussed is a particular class of stochastic games. In nonstandard problems there are additional considerations such as side constraints, multiple criteria, or mean-variance tradeoffs. Finally, it is shown that for some structured models, efficient algorithms exist. NTIS

ON ESTIMATION AND TESTING IN POISSON REGRESSION MODELS WITH OVER-DISPERSION
Klaas Poortema Sep. 1992 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(MEMO-1083; ETN-93-94123) Avail: CASI HC A03

Poisson regression models with over-dispersion are considered. Over-dispersion is modeled by introducing stochastic variables Z(sub i) such that the dependent variable Y(sub i) given Z(sub i) = z(sub i) is Poisson distributed, with expectation mu(sub i)z(sub i) where mu(sub i) depends on covariates x(sub ij) through a link function g, g(mu(sub i)) = summation(sub j) beta(sub j) x(sub ij). The usual iteration procedure for estimation can be modified. Given square root of n consistent initial estimators for beta and lambda = var(Z(sub i)) one iteration step of the new procedure is needed for the desired asymptotic normality, under quite mild conditions. The construction of square root of n consistent initial estimators of beta and lambda is considered. For testing the null hypothesis that a number of elements of beta is zero, a Wald-statistic is proposed as test-statistic. ESA

PARAMETER ESTIMATION WITH COST FUNCTION OF SECOND ORDER IN OUTPUT-ERROR-PROBLEM [PARAMETERSCHAETZUNGEN MIT QUADRATISCHER KOSTENFUNKTION BEI AUSGANGSFEHLER-PROBLEMEN]
Fro Hammelrath Jan. 1993 65 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by poor print
(DLR-FB-92-38; ETN-93-94457) Avail: Issuing Activity (European Space Agency (ESA))

A process for parameter estimation in output error problems which is derived from the maximum likelihood requirement with assumed normal distributions of measuring errors is presented. Parameter estimators are shown to be consistent under wide assumptions; with an incorrect model, the estimator converges in probability but may, in general, be biased. These results are valid for many problems with additional input noise. From consistency, it follows that in the case of sufficient smoothness the estimator may be linearized, and from this further results in asymptotic properties follow, for example influence and handling of previously filtered measurement data. This simplest case of stochastic dependency, Markovian correlation, is investigated in more detail. Additionally, it is shown that for output error problems efficient estimators exist only for linear models and Gaussian errors, and their cost functions are of second order. ESA

CURRENT DIRECTIONS IN THE VULNERABILITY/LETHALITY PROCESS STRUCTURE Final Report, Jul. 1992 - 1993
James N. Walbert, Lisa K. Roach, and Mark D. Burdeshaw Oct. 1993 40 p
(DA Proj. 1L1-62618-AH-80)
(AD-A272836; ARL-TR-296) Avail: CASI HC A03/MF A01

An important aspect of the formulation of any scientific process is the definition of the mathematical framework within which that process is considered. This mathematical basis defines the limitations of the process, provides the means for conducting analyses, and helps ensure uniformity and consistency of results. It is quite common for analytical processes to evolve over a long period of time before the underlying mathematics is fully understood and illuminated. This is the case with Vulnerability/Lethality (V/L) analysis, long considered more an art than a science. In recent years, advances have been made in the rigorous mathematical treatment of certain areas of V/L analysis. In this report, the unifying mathematical framework for all V/L analysis is defined, demonstrating how each part of a well-known process fits into this framework, and illustrating the framework's growth potential. The Degraded States Vulnerability Methodology (DSVM) will be shown to provide an important example of the rigor with which one part of a vulnerability analysis may be conducted, specifically, the formulation of target capability measures from the damaged state. MEASURE FIELDS FOR FUNCTION APPROXIMATION Memo Report
Jose L. Marroquin Jun. 1993 22 p
(Contracts N00014-91-J-4038; N00014-92-J-1879)
(AD-A272660; MIT-AIM-1433) Avail: CASI HC A03/MF A01

The computation of a piecewise smooth function that approximates a finite set of data points may be decomposed into two decoupled tasks: first, the computation of the locally smooth models, and hence, the segmentation of the data into classes that consist on the sets of points best approximated by each model, and second, the computation of the normalized discriminant functions for each induced class (which may be interpreted as relative probabilities). The approximating function may then be computed as the optimal estimator with respect to this measure field. For the first step, we propose a scheme that involves both robust regression and spatial localization using Gaussian windows. The discriminant functions are obtained by fitting Gaussian mixture models for the data distribution in the boundary of each class. We give an efficient procedure for effecting both computations, and for the determination of the optimal number of components. Examples of the application of this scheme to image filtering, surface reconstruction, and time series prediction are presented as well. DTIC

TWO VISUALLY MEANINGFUL CORRELATION MEASURES FOR COMPARING CALCULATED AND MEASURED RESPONSE HISTORIES Final Report, 1 Apr. - 30 Jun. 1993
Benjamin Whang, William E. Gilbert, and Stephen Zilliacus Jun. 1993 64 p
(AD-A273044; CARDEROCKDIV-U-SSM-67-93/15) Avail: CASI HC A04/MF A01

Two visually meaningful correlation measures are proposed for comparing calculated and measured response histories. One is an error index which is a simplification of RSS (root-sum-square) error factor, and the other is an inequality index which is a simplification of Theil's inequality coefficient. The first compares the difference between the calculated and the measured histories to the measured history. The second compares the difference between the two histories to the sum of the two. The proposed correlation measures are compared to other existing measures, namely, Geer's Error Factors, RSS Error Factor, and Theil's Inequality Coefficient for ease of interpretation and visualization. PAIRED COMPARISON MODELS WITH TIME-VARYING PARAMETERS
Mark E. Glickman May 1993 10 p
(Contract N00014-91-J-1005)
(AD-A272016; TR-ONR-C-14) Avail: CASI HC A02/MF A01

Paired comparison experiments involve comparisons among a set of objects, treatments, or competitors in blocks of size two to determine relative merits among the objects. Applications to tournament chess competition or team sports differ from the usual paired comparison framework in that competitors' abilities may change over time. A dynamic model is developed for the usual paired comparison experiment in which only a binary indicator of the preferred object is available (or trinary, if ties are allowed) and for alternative paired comparison experiments in which more information (perhaps the score) is available. Posterior distributions of the rating parameters and posterior prediction intervals for the results of future comparisons are obtained using methods that are closely related to the Kalman filter. The methodology is applied to the analysis of professional football game outcomes and to chess tournament results from the 1988-1989 World Cup. DTIC

Several practical issues regarding specifications and solution of dependability and performability models are discussed. Model types with and without rewards are compared. Continuous-time Markov chains (CTMC's) are compared with (continuous-time) Markov reward models (MRM's) and generalized stochastic Petri nets (GSPN's) are compared with stochastic reward nets (SRN's). It is shown that reward-based models could lead to more concise model specifications and solution of a variety of new measures. With respect to the solution of dependability and performability models, three practical issues were identified: largeness, stiffness, and non-exponentiality, and a variety of approaches are discussed to deal with them, including some of the latest research efforts. ON THE TOPOLOGICAL SIZE OF p-m-COMPLETE DEGREES
Marius Zimand May 1993 13 p
(Grant NSF CCR-89-57604)
(TR-459) Avail: CASI HC A03/MF A01

In this work we pursue the study of the topological size of some interesting classes of sets, focusing on complete degrees under the p-m-reduction. It is argued that neither the standard Cantor topology nor 'the next natural' superset topology are adequate for studying the topological size of classes inside NP. Instead, a combination of the two is proposed. Each finite string v belonging to Sigma(sup *) defines the basic open set U(sub v) = the set of all w belonging to Sigma(sup infinity) such that for every i less than or equal to the absolute value of v (v(i) = 1 implies w(i) = 1). Thus if we identify a set A contained in Sigma(sup *) with the binary infinite sequence w belonging to Sigma(sup infinity), representing its characteristic function, U(sub v) consists of all sets that extends the finite set encoded by v. A class of sets C contained in Sigma(sup infinity) is effectively nowhere dense if there is a recursive function f, called the witness function, such that for all v belonging to Sigma(sup *), v is a prefix of f(v) and U(sub f(v)) intersecting C = the null set. A class of sets C contained in Sigma(sup infinity) is effectively meagre (or effectively of the first category), if C is the countable union of some effectively nowhere dense sets, and is of the second category if it is not of the first category. It is shown that if P does not equal NP, then the class of NP complete sets under p-Turing reducibility is effectively meagre. In fact, by the same argument, one can show that if C is any class different from P, the class of C p-Turing complete sets is effectively meagre. In this work, we refine our tools, and admit witness functions with bounded resources. Thus if Gamma is a complexity class for functions, we say that C is Gamma-nowhere dense if the witness function is in Gamma, and we get the corresponding definitions for Gamma-meagre or Gamma-second category. The complexity class Gamma is a time complexity class, unless the word SPACE appears in the denomination of Gamma in which case Gamma is a space complexity class. We study the following question: what is the largest class Gamma such that the class of C p-m-complete sets is Gamma-second category, for different classes C. Derived from text

ACHIEVING HIGH DATA REDUCTION WITH INTEGRAL CUBIC B-SPLINES
Jin J. Chou Oct. 1993 17 p
(Contract NAS2-12961)
(NASA-CR-177628; A-94011; NAS 1.26:177628) Avail: CASI HC A03/MF A01

During geometry processing, tangent directions at the data points are frequently readily available from the computation process that generates the points. It is desirable to utilize this information to improve the accuracy of curve fitting and to improve data reduction. This paper presents a curve fitting method which utilizes both position and tangent direction data. This method produces G(exp 1) non-rational B-spline curves. From the examples, the method demonstrates very good data reduction rates while maintaining high accuracy in both position and tangent direction. Author (revised)

An accurate technique to measure the complex permittivity of materials based on a rigorous theoretical formulation of the admittance of an open-ended coaxial probe has been achieved. The technique was tested by measurements on standard solutions. The new technique was used to perform a comprehensive study of ionic solutions. The extensive data obtained led to the development of models to predict the dielectric parameters of ionic solutions at a given temperature as a function of concentration. The theoretical study and numerical techniques were extended to treat the case of a thin sample backed by a metallic plane. The technique was tested with standard solutions. Further analysis led to the development of expressions for the field in the sample adjacent to the probe. This enabled the pattern of power deposition to be determined and improved our understanding of the sampled volume. DTIC

We describe one-component statistical mechanical theories and van der Waal's effective one-component mixture model. We then show how to apply them to mixtures (containing CO2) to extract reliable unlike-pair potential involving CO2 molecules as well as their dissociation products. A more fundamental approach will require the development of a perturbation or variational theory of mixtures based on a non-additive hard-sphere mixture reference system. Recent progresses made in this direction by means of an integral equation and computer simulations is described. DOE

Avail: CASI HC A01/MF A01

A scale model and a calculation model were developed to predict traffic noise. The advantage of a scale model is that many different alternatives can be easily studied without high costs. The disadvantage is that materials properties have to be imitated according to fixed scaling rules and that the frequencies have to be increased by the scale factor. The scale model is very important in the planning of new roads and the reduction of noise, and for the improvement of calculation models. Legally prescribed calculation models were further improved in the sense that the sound waves are more closely followed. This model TOMAS is especially suited to study the interaction between the ground and noise screens. ESA

An electronic locking system was developed to remove the disadvantages of conventional mechanical door locks. The electrolock has to replace existing locks. Therefore, the techniques of Surface Mount Technology and Application Specific Integrated Circuit were applied to overcome the space limitations. The key consists of a metal rod with grip equipped with a contactless chip. When the key is inserted in the lock, a magnetic field is generated in the cylinder which induces a voltage in the chip. Therefore a battery is not required. The chip then emits inductively a code which is unique for each key. The electrolock was successfully tested. ESA

The coupling of intense laser light with plasmas is a rich field of plasma physics, with many applications. Among these are inertial confinement fusion (ICF), x-ray lasers, particle acceleration, and x-ray sources. Parametric instabilities have been studied for many years because of their importance to ICF; with laser pulses with duration of approximately a nanosecond, and laser intensities in the range 10(exp 14)-10(exp 15)W/cm(exp 2) these instabilities are of crucial concern because of a number of detrimental

effects. Although the laser pulse duration of interest for these studies are relatively long, it has been evident in the past years that to reach an understanding of these instabilities requires their characterization and analysis in picosecond time scales. At the laser intensities of interest, the growth rate for stimulated Brillouin scattering (SBS) is of the order of picoseconds, and of an order of magnitude shorter for stimulated Raman scattering (SRS). In this paper, the authors discuss SBS and SRS in the context of their evolution in picosecond time scales. They describe the fundamental concepts associated with their growth and saturation, and recent work on the nonlinear treatment required for the modeling of these instabilities at high laser intensities. Research on nonlinear acoustics has been performed during the 12-month period ending 30 September 1993. The following projects were completed: (1) propagation in a periodic waveguide, (2) finite-amplitude propagation in a medium having a distribution of relaxation processes, and (3) production of an isolated negative pulse in water. Public communication of the research was accomplished through three theses, four oral papers, one journal article published, four journal articles submitted, and one paper in a symposium proceedings. ACOUSTIC MICROSCOPY AND NONLINEAR EFFECTS IN PRESSURIZED SUPERFLUID HELIUM
A. A. Moulthrop, M. S. Muha, G. C. Kozlowski, C. P. Silva, and B. Hadimioglu 31 Aug. 1993 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-88-C-0089)
(AD-A270598; TR-0091(6925-02)-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The operation of an acoustic microscope having a resolution of 15 nm has been demonstrated. It uses as a coupling medium superfluid He-4 colder than 0.9 K and pressurized to greater than 20 bar. The microscope is now being used to image objects that show little or no contrast on a scanning electron microscope. In addition, the acoustic microscope is being used to study the properties of sound propagation in the coupling fluid. At low acoustic intensities, the coupling fluid has very low acoustic attenuation at the microscope's operating frequency (15.3 GHz), but near the focal point the acoustic intensity can be high enough that the helium behaves with extreme nonlinearity. In fact, this medium is capable of entering new regimes of nonlinear interaction. Plots of the received signal versus input power display a nearly complete pump depletion at certain input power levels and a reconversion to the pump frequency at higher power levels. Such behavior has never before been observed. We present arguments that the process underlying this nonlinear behavior is harmonic generation. DTIC

ACOUSTIC RADIATION DAMPING OF FLAT RECTANGULAR PLATES SUBJECTED TO SUBSONIC FLOWS
Karen Heitman Lyle 1 Nov. 1993 118 p Sponsored in part by NASA
(NASA-TM-109382; NAS 1.15:109382) Avail: CASI HC A06/MF A02

The acoustic radiation damping for various isotropic and laminated composite plates and semi-infinite strips subjected to a uniform, subsonic and steady flow has been predicted. The predictions are based on the linear vibration of a flat plate. The fluid loading is characterized as the perturbation pressure derived from the linearized Bernoulli and continuity equations. Parameters varied in the analysis include Mach number, mode number and plate size, aspect ratio and mass. The predictions are compared with existing theoretical results and experimental data. The analytical results show that the fluid loading can significantly affect realistic plate responses. Generally, graphite/epoxy and carbon/carbon plates have higher acoustic radiation damping values than similar aluminum plates, except near plate divergence conditions resulting from aeroelastic instability. Universal curves are presented where the acoustic radiation damping normalized by the mass ratio is a linear function of the reduced frequency. A separate curve is required for each Mach number and plate aspect ratio. In addition, acoustic radiation damping values can be greater than or equal to the structural component of the modal critical damping ratio (assumed as 0.01) for the higher subsonic Mach numbers. New experimental data were acquired for comparison with the analytical results. Author

ROTORCRAFT NOISE: STATUS AND RECENT DEVELOPMENTS
Albert R. George, Ben Wei-C. Sim, and David R. Polak 27 Dec. 1993 28 p Submitted for publication
(Grant NAG2-554)
(NASA-CR-194761; NAS 1.26:194761) Avail: CASI HC A03/MF A01

This paper briefly reviews rotorcraft noise mechanisms and their approximate importance for different types of rotorcraft in different flight regimes. Discrete noise is due to periodic flow disturbances and includes impulsive noise produced by phenomena which occur during a limited segment of a blade's rotation. Broadband noise results when rotors interact with random disturbances, such as turbulence, which can originate in a variety of sources. The status of analysis techniques for these mechanisms are reviewed. Also, some recent progress is presented on the understanding and analysis of tilt rotor aircraft noise due to: (1) recirculation and blockage effects of the rotor flow in hover; and (2) blade-vortex interactions in forward and descending flight. COMPARISON OF HIGHER ORDER MOMENT SPECTRUM ESTIMATION TECHNIQUES M.S. Thesis
Jeffrey F. McAloon Sep. 1993 123 p
(AD-A272967) Avail: CASI HC A06/MF A02

This thesis compares the detection performance of the 1-1/2 D instantaneous power spectrum (1-1/2 D (sub ips)), the bispectrum, the instantaneous higher-order moment slice (IHOMS) method, and the spectrogram for multi-component stationary signals, harmonically related stationary signals, and multi-component linear FM signals corrupted by additive white Gaussian noise. In addition, a determination of the relative processing gain between the 1-1/2 D(sub ips) method and the spectrogram is made for stationary signals in noise. The results of this thesis show that 1-1/2 D(sub ips) has a processing gain advantage over that of the spectrogram for a range of input SNR that depends upon the size of the data window. Under some conditions, the bispectrum can detect both harmonic coupling and phase coupling between the components of multi-component signals. IHOMS' ability to detect linear chirps in noise is limited to chirps having different slew rates, and the method has a significantly greater computational cost than both the spectrogram and 1-1/2 D(sub ips). APPROXIMATION TO SOUND RADIATION AND SCATTERING BY SIMPLY SUPPORTED LAYERED CYLINDER Technical Memo
J. H. James Aug. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272964; DRA-TM(USGR)93339) Avail: CASI HC A03

A theoretical approximation is obtained for calculating the acoustics of a finite multilayered anisotropic cylinder which is excited either by a mechanical force or by a plane wave at oblique incidence. The cylinder dynamics is obtained by a semi-analytical theory, and the far field acoustics by standard cylindrical baffle theory. A numerical example of steady state and transient sound radiation demonstrates an application of the model. DTIC

STABILITY CURVES FOR A THERMOACOUSTIC PRIME MOVER M.S. Thesis
Fan-Ming Kuo Jun. 1993 45 p
(AD-A272607) Avail: CASI HC A03/MF A01

The purpose of this thesis is to investigate the stability curves for and steady state waveforms in a helium filled prime mover for both the fundamental and second modes. The predicted and measured stability limits are in reasonable agreement for both modes at most mean pressures. There is, however, evidence that the stability of one mode is affected by the presence of the other. It is also observed that one mode can suppress the other. Measurements were also made on a prime mover modified such that the fundamental mode was selectively inhibited. Results indicate that the reduced fundamental amplitude allows the stability curve for the second mode to extend into the regions where the fundamental mode previously dominated. This produces a region where both modes are simultaneously excited. Analysis of the waveforms show that the resulting oscillations are quasiperiodic. DTIC

SPEED OF SOUND DATA AND RELATED MODELS FOR MIXTURES OF NATURAL GAS CONSTITUENTS
B. A. Younglove, N. V. Frederick, and R. D. McCarty Jan. 1993 99 p Sponsored by Gas Research Inst. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-200822; NIST/MONO-178) Avail: CASI HC A05

Sound speed data have been obtained for thirteen binary mixtures and four multicomponent mixtures of natural gas components using a cylindrical cavity. These data cover a temperature range from 250 to 350 K at pressures to 10 MPa. The uncertainty in the data is approximately 0.05 percent. The binary mixtures are primarily methane-rich, with ethane nitrogen, carbon dioxide, or propane as the second component. The multicomponent mixtures are representative of commercially available compositions in the United States and Europe. The data were used to develop and test mathematical models for prediction of the sound speed of natural gas mixtures, within an average uncertainty of 0.1 percent, over the ranges of pressure, temperature, and composition that encompass the major region of custody transfer for natural gas. ACTIVE CONTROL OF WAKE/BLADE-ROW INTERACTION NOISE THROUGH THE USE OF BLADE SURFACE ACTUATORS Final Report
Kenneth A. Kousen and Joseph M. Verdon Washington NASA Dec. 1993 39 p
(Contract NAS3-25425; RTOP 535-03-10)
(NASA-CR-4556; E-8227; NAS 1.26:4556) Avail: CASI HC A03/MF A01

A combined analytical/computational approach for controlling of the noise generated by wake/blade-row interaction through the use of anti-sound actuators on the blade surfaces is described. A representative two-dimensional section of a fan stage, composed of an upstream fan rotor and a downstream fan exit guide vane (FEGV), is examined. An existing model for the wakes generated by the rotor is analyzed to provide realistic magnitudes for the vortical excitations imposed at the inlet to the FEGV. The acoustic response of the FEGV is determined at multiples of the blade passing frequency (BPF) by using the linearized unsteady flow analysis, LINFLO. Acoustic field contours are presented at each multiple of BPF illustrating the generated acoustic response disturbances. Anti-sound is then provided by placing oscillating control surfaces, whose lengths and locations are specified arbitrarily, on the blades. An analysis is then conducted to determine the complex amplitudes required for the control surface motions to best reduce the noise. It is demonstrated that if the number of acoustic response modes to be controlled is equal to the number of available independent control surfaces, complete noise cancellation can be achieved. A weighted least squares minimization procedure for the control equations is given for cases in which the number of acoustic modes exceeds the number of available control surfaces. The effectiveness of the control is measured by the magnitude of a propagating acoustic response vector, which is related to the circumferentially averaged sound pressure level (SPL), and is minimized by a standard least-squares minimization procedure. EVALUATION OF A NONLINEAR METHOD FOR THE ENHANCEMENT OF TONAL SIGNAL DETECTION
Donald P. Garber Dec. 1993 27 p
(Contract NAS1-19000; RTOP 505-63-70-02)
(NASA-CR-191562; NAS 1.26:191562) Avail: CASI HC A03/MF A01

A method is presented for biasing spectral estimates to enhance detection of tonal signals against a background of broadband noise. In this method, a nonlinear average of an ensemble of individual spectral estimates is made where broadband noise energy is biased downward, pure tone energy is unbiased, and a mixture of the two is biased by an amount that depends on the ratio of tonal energy to broadband energy. The method is analyzed to provide estimates of the extent of tonal signal detection enhancement. Author

SURFACE ACOUSTIC WAVE SENSING OF VOC'S IN HARSH CHEMICAL ENVIRONMENTS
K. B. Pfeifer, S. J. Martin, and A. J. Ricco Jun. 1993 74 p
(Contract DE-AC04-76DP-00789)
(DE93-040721; SAND-93-0070) Avail: CASI HC A04/MF A01

The measurement of VOC concentrations in harsh chemical and physical environments is a formidable task. A surface acoustic wave (SAW) sensor has been designed for this purpose and its construction and testing are described in this paper. Included is a detailed description of the design elements specific to operation in 300 C steam and HCl environments including temperature control, gas handling, and signal processing component descriptions. In addition, laboratory temperature stability was studied and a minimum detection limit was defined for operation in industrial environments. Finally, a description of field tests performed on steam reforming equipment at Synthetica Technologies Inc. of Richmond, CA is given including a report on destruction efficiency of CCl4 in the Synthetica moving bed evaporator. Design improvements based on the field tests are proposed. DOE

THREE DIMENSIONAL ULTRASONIC IMAGING
G. H. Thomas, S. Benson, and S. Crawford Mar. 1993 12 p Presented at the Society of Photo-Optical Instrumentation Engineers (SPIE) OE/Aerospace Science and Sensing Meeting, Orlando, FL, 11-16 Apr. 1993
(Contract W-7405-eng-36)
(DE93-040549; UCRL-JC-113437; CONF-930445-25) Avail: CASI HC A03/MF A01

Ultrasonic nondestructive evaluation techniques interrogate components with high frequency acoustic energy. A transducer generates the acoustic energy and converts acoustic energy to electrical signals. The acoustic energy is reflected by abrupt changes in modulus and/or density which can be caused by a defect. Thus defects reflect the ultrasonic energy which is converted into electrical signals. Ultrasonic evaluation typically provides a two dimensional image of internal defects. These images are either planar views (C-scans) or cross-sectional views (B-scans). The planar view is generated by raster scanning an ultrasonic transducer over the component and capturing the amplitude of internal reflections. Depth information is generally ignored. The cross-sectional view is generated by scanning the transducer along a single line and capturing the amplitude and time of flight for each internal reflection. The amplitude and time of flight information is converted into an image of the cross section of the component where the scan was performed. By fusing the C-scan information with the B-scan information a three dimension image of the internal structure of the component can be produced. The three dimensional image can be manipulated by rotating and slicing to produce the optimal view of the internal structure. The high frequency ultrasonic energy requires a liquid coupling media and thus applications for imaging in liquid environments are well suited to ultrasonic techniques. Examples of potential ultrasonic imaging applications are Inside liquid filled tanks, inside the human body, and underwater. DOE

(PB93-205326; HMMH-290940.04-2) Avail: CASI HC A03

The results are ultimately used to estimate the potential for damage to a wide variety of cultural resources from operations of commercial helicopters. Comparison of measured vibration levels with criteria for damage based on structural velocities will provide a family of restrictions on aircraft operations in the vicinity of sensitive structures. Such restrictions could take the form of minimum separation distances and prohibited maneuvers for helicopters. The results of the study would be presented in a report as a set of recommended procedures for helicopter operations to avoid damage to prehistoric, historic, sensitive, and conventional structures. INTERFACE REFLECTION OF SPHERICAL ACOUSTIC WAVES IN THE FIRST- AND SECOND-ORDER RATIONAL PARABOLIC APPROXIMATIONS AND THEIR ARTIFACTS
M. V. DeHoop and A. T. DeHoop 1992 48 p Prepared in cooperation with Koninklijke/Shell Exploratie en Produktie Lab., Rijswijk, Netherlands
(PB93-215424; ET/EM-1992-17) Copyright Avail: CASI HC A03/MF A01

The accuracy of the first- and second-order rational parabolic approximations of the 'vertical' slowness and the nature of the artifacts associated with them in the space-time solutions to the acoustic wave equations in a fluid medium are investigated. In particular, the reflection of an impulsive, point-source generated, spherical wave against the boundary with a medium with a higher wave speed is analyzed. From the space-time Green's functions in the relevant two-media configuration, evaluated with the aid of the modified Cagniard method, it is found that, instead of generating the real, physical head wave, the approximations generate artificial head-wavelike arrivals. The analysis makes explicit in which regions of space and in which time interval the artifacts show up and of what nature they are. Numerical results are presented. NTIS

TRANSIENT ACOUSTIC WAVE MODELING: HIGHER-ORDER WKBJ ASYMPTOTICS AND SYMBOLICAL MANIPULATION (REVISED)
M. D. Verweij 1992 47 p
(PB93-215432; ET/EM-1992-18) Copyright Avail: CASI HC A03/MF A01

A combination of WKBJ asymptotics and the Cagniard-De Hoop method is used to determine the space-time domain acoustic wavefield in a continuously horizontally layered configuration. First, a Laplace transformation with a real and positive transform parameter is applied with respect to the time coordinate, followed by a two-dimensional Fourier transformation with respect to the horizontal coordinates. Using the integral equations of the resulting transform domain problem, a recurrence scheme is derived for the coefficients of the WKBJ asymptotic expansions of the transform domain solutions. This scheme is well-suited for implementation in a symbolical manipulation program. The transformation of the resulting higher order WKBJ asymptotic representations back to the space-time domain is performed with the aid of the Cagniard-De Hoop method, which is particularly efficient in this case. If both the source and the receiver are located in one homogeneous halfspace of the configuration, the Cagniard-De Hoop method allows for an almost completely analytical transformation back to the space-time domain. Avail: CASI HC A02/MF A01

This document reviews the physics assumptions and input embedded in ISAJET 7.0/ISASUSY 1.0 which is relevant for simulating fundamental processes within the framework of the Minimal Supersymmetric Model (MSSM) at p(bar p) and pp colliders. After a brief discussion of the underlying MSSM framework, the authors discuss event simulation and list the particle production processes and decay modes that have been incorporated into the calculations. They then describe how to set up and run an ISAJET/ISASUSY job, as well as the user input and output formats. The ISAJET program is sufficiently flexible that some non-miminal supersymmetry scenarios may be simulated as well. Finally, plans for future upgrades which include the extension to e(sup +)e(sup -) collisions are listed. DOE

(AD-A271013; ARO-27766.2-PH) Avail: CASI HC A01

Methods for position measurement of moving atoms with ultrahigh spatial resolution were developed, based on resonance imaging in a spatially varying potential with a steep gradient. Using a spatially light-shift due to an off-resonant focused optical field, spatial resolution of 200 nanometers, with a few percent linearity over several microns was obtained. Centroids of narrow spatial features, which are created and probed in the experiments, are determined with an accuracy of +/- 20 nanometers. Ultimately, with higher gradients and single atom detection, uncertainty principle limited spatial resolution of a few nanometers will be attainable. These methods will have applications in the characterization of atom-optical elements, and in the development of new methods of ultrahigh resolution neutral atom lithography. DTIC

ELECTRON REACTIONS IN NONPOLAR LIQUIDS: PRESSURE EFFECTS
R. A. Holroyd 1993 18 p Presented at the NATO Advanced Study Institute: Linking the Gaseous and Condensed Phases of Matter - the Behavior of Slow Electrons, Patras, Greece, 5-18 Sep. 1993
(Contract DE-AC02-76CH-00016)
(DE93-040328; BNL-49429; CONF-930993-2) Avail: CASI HC A03/MF A01

Theory predicts that electron energy levels in nonpolar molecular hydrocarbons should increase in energy with density/pressure increase, and therefore, electron attachment rates in solution should change with pressure. Studies of pressure effect on electron mobility show that some contraction occurs around trapped electrons, but more contraction occurs around ions in hydrocarbons. After a brief discussion of pressure effects on electron energy levels and mobility, this paper reports studies of electron attachment reactions of N2O, CO2, and n-C5F12 in tetramethylsilane, and of toluene, benzene, CO2, and 1,3-butadiene in several solvents. ENCOUNTERS OF H AND D ATOMS WITH O2 IN WATER: RELATIVE DIFFUSION AND REACTION RATES
P. Han and D. M. Bartels 1993 14 p Presented at the Ultrafast Reaction Dynamics and Solvent Effects, Asnieres Sur Oise, France, 11-15 May 1993
(Contract W-31-109-eng-38)
(DE93-018587; ANL/CHM/CP-79706; CONF-9305254-1) Avail: CASI HC A03/MF A01

Diffusive encounters of H and D atoms with O2 in water are investigated with the time-domain EPR free induction decay attenuation technique. Given the paramagnetic triplet ground state of the O2 molecule, it is expected that all H-O2 encounters will contribute to spin dephasing, regardless of whether reaction to form HO2 occurs. In H2O the second-order spin-spin dephasing rate of H in the presence of O2 is 1.94 x 10(exp 10) M(exp -1) sec(exp -1) at 25 C, with an activation energy of 11.22 +/- 0.33 kJ/mole between 8 and 60 C. In a mixture of 90% D2O and 10% H2O, H atom dephasing is marginally slower in the same temperature range. Dephasing of D atoms in 90% D2O is about 5-10% slower than H, indicating that diffusion of D is slower than H. The results are analyzed in terms of other available data concerning H and O2 diffusion and the reaction rate in water. It seems clear that neither the Stokes Einstein hydrodynamic theory nor classical activated rate theory applies to the diffusion of light hydrophobic gases in water. The authors tentatively conclude that H-O2 spin exchange is slightly less efficient than can be predicted in the theoretical diffusion limit. DOE

TESTING DOUBLE IONIZATION MECHANISMS WITH HIGHLY-CHARGED IONS
J. A. Tanis 1992 9 p Presented at the 6th International Conference on Physics of Highly Charged Ions, Manhattan, KS, 28 Sep. - 2 Oct. 1992
(Contract DE-FG02-87ER-13778)
(DE93-018750; CONF-920948-17) Avail: CASI HC A02/MF A01

Double ionization of He target atoms by intermediate- to high-velocity charged ions is considered in terms of two mechanisms: a two-step (TS) process in which both target electrons are removed in separate direct interactions with the projectile, and a one-step mechanism in which one electron is liberated in a single projectile-target interaction followed by subsequent 'shake-off' (SO) of the second electron. Measured double-to-single ionization ratios are used to exhibit and test the underlying mechanisms of double ionization. It is found that these ratios exhibit a high degree of universality as a function of v/q, where v is the velocity of the ion and q is its charge. The results strongly suggest that the important factor in determining the regions of validity for TS and SO is the ionic charge divided by the impact velocity and not just the impact velocity itself. DOE

THE MULTICOMPONENT LINESHAPE OF THE ANHARMONIC A(1)(TO) PHONON IN PbTiO3
C. M. Foster, Z. Li, M. Grimsditch, S. K. Chan, and V. G. Karpov Jul. 1993 7 p Presented at the 8th International Meeting on Ferroelectricity, Gaithersburg, MD, 8-13 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-018995; ANL/MSD/CP-78121; CONF-930852-1) Avail: CASI HC A02/MF A01

Detailed Raman studies of the optical phonons in single-crystal PbTiO3

indicate that the frequencies and symmetry assignments in the literature must be revised. In this study, all vector-k approximately equal to zero optical phonon modes are directly observed and are shown to rigorously obey Raman selection rules. The angular dependence of the phonon frequencies indicates that the energy of the lowest frequency A(sub 1)(TO) mode, which exhibits an anomalous anharmonisity-induced lineshape, is higher than the energy of the lowest frequency E(LO) mode at 300 K. EXAMINATION OF LOW LEVEL MAGNETIC DIPOLE INTENSITIES IN THE TRANSITION NUCLEI Sm-148, Sm-150, Sm-152 AND Sm-154, WITH INELASTIC PHOTON SCATTERING AT S-DALINAC Ph.D. Thesis [UNTERSUCHUNG NIEDRIGLIEGENDER MAGNETISCHER DIPOLSTAERKE IN DEN UEBERGANGSKERNEN 148, 150, 152, 154SM MIT INELASTISCHER PHOTONENSTREUUNG AM S-DALINAC]

Wolfgang P. Ziegler 1990 95 p In GERMAN

(ETN-93-95069) Avail: CASI HC A05/MF A01

The intensities of magnetic dipole transitions in scissor mode excitation energy area are estimated for isotopes of vibration and rotation nuclei. Experiments were performed with the nuclear resonance fluorescence method at samarium isotopes, using a bremsstrahlung source and two germanium detectors, designed for a supraconductor linear accelerator. The results show a linear relation between the M1 sum intensity and the square of mass deformation; properties of mean excitation mode are examined in the framework of the neutron proton deformation model, in which separated neutron and proton deformation parameters were introduced. Sum intensities were calculated with the interacting free boson model and are found to be underestimated. The experimental value of median excitation energy is shown to agree with the predicted value in the monopole quadrupole pairing model. ESA

COLLISIONS OF MOLECULES WITH CLUSTERS: A QUASICLASSICAL STUDY

J. Jellinek and Z. B. Guevenc 1993 15 p Presented at the European Research Conference in Physics: Fundamental Aspects of Clusters, Elounda, Greece, 26 May - 2 Jun. 1993

(Contract W-31-109-eng-38)

(DE93-018614; ANL/CHM/CP-79761; CONF-9305157-1) Avail: CASI HC A03/MF A01

Presented are results of a quasiclassical simulation study of processes induced by a collision of a D2 molecule with a Ni13 cluster. Focus is on the reactive channel, i.e., dissociative adsorption, of the molecule. Dependence on factors such as the collision energy, initial (quantized) rovibrational state of the molecule, and structure and temperature of cluster are analyzed. Direct and indirect (involving formation of transient complexes -- resonances) reaction pathways are considered and characterized quantitatively. The authors illustrate how multidimensional potential energy surfaces describing cluster-molecule interactions can be analyzed in terms of a reduced set of relevant degrees of freedom and the topologies of these surfaces correlated with dynamical phenomena extracted from the calculations. The complex problem of 'tuning' the cluster-molecule interaction potential using experimental data is addressed, and a specific example of such 'tuning' is given. It underscores the crucial role of the intimate interplay between theory and experiment, especially in the field of clusters where, because of the large number of degrees of freedom involved, first principle calculations are (and will remain) of limited feasibility. More generally, the analysis and the discussion presented show that the phenomena and problems relevant for cluster-molecule collisions -- a new research area by all accounts -- have much in common with those encountered in nucleus-nucleus, atom-atom, atom-molecule, and molecule-molecule collisions -- research fields with a considerable history. STUDY OF MECHANISMS FOR LONG WAVELENGTH SCHOTTKY-BARRIER INFRARED DETECTORS Final Technical Report

Leo J. Schowalter Jul. 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F19628-91-K-0030)

(AD-A270538; RL-TR-93-135) Avail: CASI HC A03

We have studied ballistic electron transport across metal layers and metal/semiconductor interfaces using a scanning tunneling microscope to inject electrons with a controlled energy into a thin metal film, which allows measurements (with spatial resolution approaching 1 nm) of (1) the local Schottky barrier (SB) height, (2) ballistic mean free paths of energetic electrons (or holes), and (3) transmission probability of hot carriers across the metal/semiconductor interface. The attenuation length of hot electrons (1.5 eV above the Fermi level) in PtSi is measured as approximately 4 nm. We also used BEEM (Ballistic-electron-emission Microscopy) to observe the sharp onset of inelastic scattering mechanisms in Au/Si and PtSi. We observe that the derivative BEEM spectrum of Au/Si (001) n-type is rich with features which may correspond to either M/S interface states or to states in the semiconductor bandgap near the interface. We suggest that these interface scattering processes occur also for other M/S systems. Our experimental BEEM studies indicate that hot electron transport is diffusive in the sense that electrons will scatter elastically many times before an inelastic event will occur. We succeeded in constructing a low temperature (liquid nitrogen temperatures) BEEM head and have taken BEEM spectra of PtSi on P-type Si. DTIC

NEW RELATIVISTIC S-MATRIX RESULTS FOR SCATTERING -- BEYOND THE USUAL ANOMALOUS FACTORS/BEYOND IMPULSE APPROXIMATION

R. H. Pratt (Pittsburgh Univ., PA.), P. M. Bergstrom, Jr. (Pittsburgh Univ., PA.), and L. Kissel Aug. 1993 49 p Presented at the International Conference on Anomalous Scattering, Hamburg, Germany, 17-21 Aug. 1992

(Contract W-7405-eng-48)

(DE93-019148; UCRL-JC-114583; CONF-9208186-5) Avail: CASI HC A03/MF A01

The relativistic second-order S-matrix elements for photon-atom scattering have been successfully calculated with numerical methods within the independent particle approximation (IPA). This permits an assessment of the validity of simpler approximate predictions which are commonly used and it offers the possibility of improved tabulations of theoretical predictions. A variety of unresolved issues remain, some associated with the relativistic theory, some with IPA. The systematic use of the second-order S-matrix in calculations of Rayleigh scattering from isolated atoms has led to significant progress in understanding this process and to a wide range of agreement with experiment. The energy and angular dependence of anomalous factors and the importance of relativistic, higher-multipole and bound-bound contributions in their calculation is better understood. However correlation effects must also be included to obtain predictions for the near-edge region, such extensions of the present S-matrix calculation have been discussed but few results are available so far. Existing empirical approaches can be assessed in regard to their success in dealing with known IPA features. We have recently calculated the relativistic second-order S-matrix element for Compton scattering and have begun to try to understand this process in different regions. We can discuss this when the more complete calculation confirms the standard Compton peak. In the softer part of the spectrum impulse approximation fails. There can be resonant Raman peaks, and in the soft-photon region the spectrum is infrared divergent, proportional to the photoeffect angular distribution. This means the traditional incoherent scattering factor is undefined in the absence of a low-energy detector efficiency cutoff. DOE

RELATIVISTIC CALCULATIONS OF THE SUPERHEAVY NUCLEUS (SUP 298)114

Hielke Freerk Boersma 19 Jan. 1993 8 p Submitted for publication

(KVI-969; ETN-93-94818) Avail: CASI HC A02/MF A01

Ground state properties of the superheavy nucleus with N = 184 and Z = 114, (sup 298)114 were investigated, using conventional relativistic mean field theory and density dependent mean field theory, which reproduces Dirac-Brueckner calculations in nuclear matter. There are strong indications that the next doubly magic nucleus beyond Pb-208 is (sup 298)114. The calculations provide support for N = 184 and Z = 114 being magic numbers. Density dependent mean field theory does not predict (sup 298)114 to be stable against beta decay. ESA

LABORATORY STUDIES OF LOW TEMPERATURE RATE COEFFICIENTS: THE ATMOSPHERIC CHEMISTRY OF THE OUTER PLANETS Final Report
Stephen R. Leone Dec. 1993 3 p
(Grant NAGw-2438)
(NASA-CR-193485; NAS 1.26:193485) Avail: CASI HC A01/MF A01

The objectives are to measure laboratory rate coefficients for key reactions of hydrocarbon molecules and radicals at low temperatures, which are relevant to the atmospheric photochemistry of Saturn, Jupiter, and Titan. Upcoming NASA planetary missions, such as Cassini, will probe the atmosphere of Titan in more detail, offering an excellent opportunity to test kinetic models and to establish fiducial standards for using kinetic models to interpret various parameters of the outer planets. Accurate low temperature kinetic data, which are presently lacking, may require crucial revisions to the rates of formation and destruction and are of utmost importance to the success of these efforts. In this program, several key reactions of ethynyl radicals (C2H) with acetylene (C2H2), methane (CH4), and oxygen (O2), down to temperatures of 170 K were successfully investigated. The experimental apparatus developed in our laboratory for measuring reaction kinetics at low temperatures consists of a laser photolysis/infrared probe laser setup. The rate measurements are carried out as a function of (low) temperature with a transverse flow cell designed specifically for these studies. A 193 nm argon fluoride pulsed excimer laser is used to photolyze a suitable precursor molecule, such as acetylene to produce C2H, and a high resolution, tunable infrared F-center laser (2.3-3.35 mu m) probes the transient concentrations of the radical species directly in absorption to extract the kinetic rate coefficients.

The authors have implemented a particle-in-cell method on a 32 transputer computing network. The tests have shown that the performance of this system reaches 1/8 of the equivalent one for the code optimized for a CRAY Y-MP/2E. The system performance analysis shows that this network remains cost-effective until expanded approximately up to 100 transputers. This transputer equipment has provided an efficient computational tool for investigating a novel physical phenomenon -- a collisionless mechanism for separation of different elements in colliding plasma beams. Deep inelastic neutron scattering has been used to measure the neutron Compton profile (NCP) of a series of condensed He-4 samples at densities from 28.8 atoms/nm(exp 3) (essentially the minimum possible density in the solid phase) up to 39.8 atoms/nm(exp 3) using a chopper spectrometer at the Argonne National Laboratory Intense Pulsed Neutron Source. At the lowest density, the NCP was measured along an isochore through the hcp, bcc, and normal liquid phases. Average atomic kinetic energies are extracted from each of the data sets and are compared to both published and new path integral Monte-Carlo (PIMC) calculations as well as other theoretical predictions. In this preliminary analysis of the data, account is taken of the effects of instrumental resolution, multiple scattering, and final-state interactions. Both our measurements and the PIMC theory show that there are only small differences in the kinetic energy and longitudinal momentum distribution of isochoric helium samples, regardless of their phase or crystal structure. CHARGE COLLECTORS FOR THE OMEGA UPGRADE
B. Yaakobi Aug. 1993 11 p
(Contract DE-FC03-85DP-40200)
(DE93-019684; DOE/DP-40200/267) Avail: CASI HC A03/MF A01

Charge collectors placed at several distances from the target measure the current of ions resulting from target disassembly and expansion as a function of arrival time at the detector. Since the expanding plasma is neutral, comprising both electrons and ions moving together, the role of the charge collector is to separate out the electrons, so that the net ion current can be measured. The time-integrated current, or the total charge, can yield the total mass ablated from the target, provided the ionic charge Z is known. From the total ablated mass, the mass ablation rate during the target implosion can be estimated. This quantity provides a useful gauge of the combined effects of absorption, heat conduction, and hydrodynamic efficiency in target interactions. In principle, one charge collector can yield useful results because the author assumes spherical symmetry of the expansion (this question is addressed directly by the plasma calorimeters of which there are many around the target). In practice there will be four charge collectors, two at the tank wall (distance R from the target) and two in an extension tube, at a distance of about 2R from the target. The reason for the two different distances is to check that complete charge separation within the detector has been achieved. A signature of such separation will be to verify that the current falls off as I/R(exp 2) with distance from the target. Since the separation can be inadequate due to space charges within the detector, the farther detector, having smaller charge density, will be more reliable. The two pairs will be oriented at about 90 degrees with respect to each other (say, east and north) to give a rough idea on the isotropy. DOE

B PRODUCTION AT D0
T. G. Trippe Jun. 1993 4 p Presented at the 28th Conference on Quantum Chromodynamics and High Energy Hadronic Interactions, Les Arcs, France, 13-27 Mar. 1993

(Contract DE-AC03-76SF-00098)
(DE93-019250; LBL-34294; CONF-930363-6) Avail: CASI HC A01/MF A01

The D(0) detector is well suited for some aspects of B physics. The muon system is capable of triggering on muons with p(sub T) down to 3 GeV/c, is dense and compact to suppress backgrounds from punchthrough and decay in flight, and covers a large pseudorapidity range--the absolute value of eta is less than 3.3. This allows the study of B production in muon and multimuon channels over a wide p(sub T) and eta range, which should provide information about gluon densities at small x. The muon inclusive p(sub T) distribution is shown. Dimuon mass and charge correlations are analyzed to separate production and decay processes. B production in the inclusive B yields J/psi chi as well as J/psi and gamma production are discussed. B(bar-B) mixing is studied using like-sign dimuon events. DOE

HIGH RESOLUTION INFRARED SPECTROSCOPY OF FORMAMIDE AND DEUTERATED FORMAMIDE IN A MOLECULAR BEAM Technical Report
Christopher L. Brummel, Meihua Shen, Kevin B. Hewett, and Laura A. Philips 26 Oct. 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1971)
(AD-A271986; TR-9) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

High resolution infrared spectra of formamide and deuterated formamide (DCONH2) were collected using molecular beam optothermal spectroscopy. The spectrum of formamide was found to be perturbed such that each rotational transition was split into two peaks. The splitting was absent in the spectrum of deuterated formamide. The large splitting in the spectrum of formamide (approximately 0.7/cm) prevented an accurate deconvolution of the spectrum into zeroeth order bright and dark states. A list of the possible coupling modes is presented. The coupling, however, is not well represented as a simple coupling of two rigid rotors. DTIC

HIGH RESOLUTION INFRARED SPECTROSCOPY OF CYCLOBUTANE: A STUDY OF VIBRATIONAL MODE COUPLING INVOLVING LARGE AMPLITUDE, LOW FREQUENCY MODES
H. Li, C. C. Miller, and Laura A. Philips 26 Oct. 1993 42 p
(Contract N00014-90-J-1971)
(AD-A271987; TR-11) Avail: CASI HC A03/MF A01

The high resolution IR spectrum of cyclobutane in a supersonic molecular beam was obtained for the region of 2981 to 2991/cm. The spectrum reveals four overlapping bands suggestive of vibrational mode coupling in the C-H stretching region. Ground state combination differences demonstrate that these bands originate from 2 different ground states, the symmetric and asymmetric ring puckering states. Evidence of vibrational mode coupling is present in all four bands. The coupling depends on both J and the symmetry of the puckering state. A model coupling scheme involving two qualitatively different types of couplings is developed to explain the observed spectrum. Symmetry restrictions and the interaction between molecular rotation and ring puckering qualitatively accounts for the dramatically different coupling behavior between the two ring puckering states. F-SPIN CONCEPT AND g-BOSONS IN THE INTERCEDING BOSON MODEL Ph.D. Thesis [F-SPIN-KONZEPT UND G-BOSONEN IM MODELL WECHSELWIRKENDER BOSONEN]
Ottfried Engel 1990 96 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-93607) Avail: CASI HC A05

The F-spin concept is introduced in the interacting boson model to take into account fermion structure by considering bosons as fermion pairs. Majorana operator was designed as the quadratic Casimir operator, which

is diagonal on the subspaces of defined permutation symmetry and can energetically separate states of different permutation symmetry of the neutron-proton product wave function. Since the model is restricted to s and d bosons, mixed symmetry states must be defined. Excitation energies and boson densities were calculated and compared with experimental data. The validity of microscopic interpretation in the model was discussed from the point of view of particle freedom degree. ESA

APPLICATION OF MOLECULAR MODELING TO BIOLOGICAL PROCESSING Final Report, Jan. - Apr. 1992

Alfred H. Lowrey (Naval Research Lab., Washington, DC.), George R. Famini, and Charles Wick Jul. 1993 32 p

(AD-A272612; ERDEC-TR-029) Avail: CASI HC A03/MF A01

Detailed understanding of the molecular basis for biological processes is now available through computational modeling techniques. Advances in computational algorithms and technology allow applications to large biological macromolecules and permits the study of such problems as binding mechanisms, chemical reactivity, structural and conformational effects, and simulations of molecular motions. Recent crystallographic data provides access to detailed structural information that allows analysis and comparison of various computational techniques. Preliminary semiempirical studies on N-acetylneuraminic acid are presented as an example of computational studies on binding mechanisms. N-acetylneuraminic acid is a substituted carbohydrate, which is a recognition site for binding of proteins (i.e., cholera toxin). These calculations provide some insight into electronic effects on bin in a crystal complex and the effect of the molecular charge on hydrogen bonding the crystal complex. DTIC

ELECTRON EMISSIONS IN LOW ENERGY Ar(q+)-Ar COLLISIONS

J. Vancura and V. O. Kostroun 1992 4 p Presented at the 6th International Conference on Physics of Highly Charged Ions, Manhattan, KS, 28 Sep. - 2 Oct. 1992

(Contract DE-FG02-86ER-13519)

(DE93-040285; CONF-920948-19) Avail: CASI HC A01/MF A01

The spectra of electrons emitted Ar(q+) on Ar (8 less than or = q less than or = 16) collisions at 2.3 q keV were measured in the 30 to 400 eV energy range. With the exception of Ar(8+) on Ar, the overall appearance of the electron spectra is quite similar, suggesting that the same mechanism is responsible for the observed features. One possible mechanism is the delocalization of the 3p and 3s target electrons during the collision. The resulting molecular state either deexcites by Auger transitions during the collision, or strands two or more electrons on the projectile in an excited state. This state in turn deexcites by Auger transitions. DOE

PHOTOEMISSION AND THE ELECTRONIC PROPERTIES OF HEAVY FERMIONS: LIMITATIONS OF THE KONDO MODEL

J. J. Joyce, A. J. Arko, A. B. Andrews, R. I. R. Blyth, J. D. Thompson, D. Fisk, P. S. Riseborough, P. C. Canfield, C. G. Olson, and P. G. Benning 1993 13 p Presented at the International Conference on Strongly Correlated Electron Systems, La Jolla, CA, 16-19 Aug. 1993

(Contract W-7405-eng-36)

(DE93-040191; LA-UR-93-3041; CONF-930865-8) Avail: CASI HC A03/MF A01

The electronic properties of Yb-based heavy fermions have been investigated by means of high resolution synchrotron radiation photoemission and compared with predictions of the Kondo model. The Yb heavy fermion photoemission spectra show massive disagreement with the Kondo model predictions (as calculated within the Gunnarsson-Schonhammer computational method). Moreover, the Yb heavy fermion photoemission spectra give very strong indications of core-like characteristics and compare favorably to purely divalent Yb metal and core-like Lu 4f levels. The heavy fermions YbCu2Si2, YbAgCu4, and YbAl3 were measured and shown to have lineshapes much broader and deeper in binding energy than predicted by the Kondo model. The lineshape of the bulk component of the 4f emission for these three heavy fermion materials was compared with that from Yb metal and the Lu 4f levels in LuAl3; the heavy fermion materials show no substantive spectroscopic differences from simple 4f levels observed in Yb metal and LuAl3. Also, the variation with temperature of the 4f lineshape was measured for Yb metal and clearly demonstrates that phonon broadening plays a major role in 4f level lineshape analysis and must be accounted for before considerations of correlated electron resonance effects are presumed to be at work. HADRONIC MOLECULES AND SCATTERING AMPLITUDES FROM THE NONRELATIVISTIC QUARK MODEL

T. Barnes 1993 7 p Presented at the Conference on Hadron, Como, Italy, 21-25 Jun. 1993

(Contract DE-AC05-84OR-21400)

(DE94-000377; CONF-9306134-2) Avail: CASI HC A02/MF A01

This report summarizes recent calculations of low-energy hadron-hadron scattering amplitudes in the nonrelativistic quark potential model, which assume that the scattering mechanism is a single interaction (usually OGE) followed by constituent interchange. We refer to the scattering diagrams as 'quark Born diagrams.' For the cases chosen to isolate this mechanism, I=2 pi pi, I=3/2 K pi, KN and NN, the results are usually in good agreement with experimental S-wave scattering amplitudes given standard potential-model parameters. These calculations also lead to predictions of vector-vector bound states, one of which may be the theta(1710). This assignment can be tested by searches for K bar-K pi pi and phi pi(exp 0) gamma decay modes of the theta(1710). DOE

PHOTOABSORPTION AND COMPTON SCATTERING IN IONIZATION OF HELIUM AT HIGH PHOTON ENERGIES

L. R. Andersson (Tennessee Univ., Knoxville.) and J. Burgdoerfer (Tennessee Univ., Knoxville.) 1993 8 p Presented at the 18th International Conference on the Physics of Electronic and Atomic Collisions, Aarhus, Denmark, 21-27 Jul. 1993

(Contract DE-AC05-84OR-21400)

(DE94-000380; CONF-930711-12) Avail: CASI HC A02/MF A01

Production of singly and doubly charged helium ions by impact of keV photons is studied. The ratio R(sub ph) = sigma(sub ph)(sup ++)/sigma(sub ph)(sup +) for photoabsorption is calculated in the photon-energy range 2-18 keV using correlated initial- and final-state wave functions. Extrapolation towards asymptotic photon energies yields R(sub ph)(omega goes to infinity) = 1.66% in agreement with previous predictions.

Ionization due to Compton scattering, which becomes comparable to photoabsorption above omega approximately 3 keV, is discussed. DOE

SEARCHING FOR HIGH BARYON DENSITY AT THE AGS WITH ARC
S. H. Kahana, T. J. Schlagel, and Y. Pang Aug. 1993 4 p Presented at the 10th International Conference on Ultra-Relativistic Nucleus-Nucleus Collisions, Borlenge, Sweden, 20-24 Jun. 1993
(Contract DE-AC02-76CH-00016)
(DE93-041155; BNL-49432; CONF-930636-1) Avail: CASI HC A01/MF A01

A relativistic cascade ARC is used to analyze heavy ion experiments at the AGS. In particular predictions from ARC for Au on Au at 11.6 GeV/c have proved to be remarkably accurate. Going to lower energies and inserting a phenomenological equation of state into the cascade should lead to information about the interesting region of high baryon density. DOE

ELECTRON EMISSION FROM NANOMETER-SIZE METALLIC CLUSTERS: ELECTRONIC STATES AND STRUCTURAL STABILITY OF SUPPORTED Au CLUSTERS
M. E. Lin, A. Ramachandra, R. P. Andres, and R. Reifenberger 1992 12 p Presented at the North Atlantic Treaty Organization-ARW Meeting on Manipulation of Atoms Under High Fields and Temperatures, Lyon, France, 6-10 Jul. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG02-84ER-45162)
(DE93-040184; CONF-9207218-1) Avail: CASI HC A03

Techniques developed to measure the thermodynamic and electronic properties of a single metallic cluster with nanometer-size dimensions are described. Using these techniques, experiments that resolve the quantized energy spectrum of electrons in a nanometer-size cluster of metallic atoms at room temperature have been performed. Studies on the stability of the electron emission current from an individual nanometer-size cluster supported on a tungsten tip have been performed to learn more about the intrinsic stability of these nanometer-size objects. The data show abrupt jumps between different emission states that are revisited as time progresses. This phenomenon is attributed to a rearrangement of the duster structure and/or orientation on the substrate and provides new evidence of multiple 'isomeric' structures for small clusters of metallic atoms. DOE

RECENT RESULTS ON TOP, BOTTOM AND EXOTIC PHYSICS AT THE TEVATRON
N. M. Shaw Aug. 1993 16 p Presented at the Workshop on Physics at Current Accelerators and the Supercollider, Argonne, IL, 2-5 Jun. 1993
(Contract DE-AC02-76CH-03000)
(DE94-000578; FNAL/C-93/263-E; CONF-9306176-6) Avail: CASI HC A03/MF A01

A summary of results from the recently concluded 1991-1993 Tevatron run is presented. Selected topics from b physics and exotic particle searches from the CDF and D0 collaborations are reviewed. Preliminary results from the CDF top search, using 12pb(exp -1) from the 1992-1993 run, are given. In particular, the lepton + b-tag and dilepton analyses are discussed. Preliminary results from the CDF dilepton analysis places a lower limit on the top quark mass of 108GeV/c(exp 2) at the 95% C.L. DOE

A measurement of the nucleon spin asymmetries from deep inelastic scattering of polarized electrons by polarized He-3 has been performed. The neutron spin structure function g(sub 1)(exp n) is extracted and used to test the Bjorken sum rule. The neutron integral assuming a simple Regge theory extrapolation at low x is integral (sub 0)(sup 1)g(sub 1)(exp n)(x)dx = -0.022 (plus/minus) 0.011. Combined with the EMC proton results, the Bjorken sum rule predicts a neutron integral of integral(sub 0)(sup 1) g(sub 1)(exp n)(x)dx = -0.065 (plus/minus) 0.018. DOE

MEASUREMENT OF THE B MESON AND b QUARK CROSS-SECTION IN (-p)p COLLISIONS AT THE SQUARE ROOT OF s = 1.8 TeV USING THE EXCLUSIVE DECAYS B(+) AND B(EXP 0) YIELDS J/PSIK*(EXP 0)
Aug. 1993 9 p Presented at the Symposium on Lepton and Photon Interactions, Ithaca, NY, 10-15 Aug. 1993
(Contract DE-AC02-76CH-03000)
(DE93-019907; FNAL/C-93/200-E; CONF-930823-8) Avail: CASI HC A02/MF A01

The production of b quarks in p(bar p) collisions in the Collider Detector at Fermilab (CDF), using the B meson decay channels B(+) yields J/(psi)K(+) and B(sup 0) yields J/(psi)K(*0), with J/(psi) yields mu(+)mu(-) and K(*0) yields K(+)pi(-), and their charge conjugates. Measurements of the B meson with b quark cross-sections integrated above minimum transverse momentum values in the rapidity range absolute value of y is less than 1 are described. The first fully differential B meson cross-section measurement in the same rapidity range is also reported. Comparison is made to previous CDF measurements and to the O(alpha(sub s)(sup 3)) theoretical calculations. DOE

SEARCH FOR EXCITED QUARKS IN p(-p) COLLISIONS AT THE SQUARE ROOT OF s = 1.8 TeV
Aug. 1993 12 p Presented at the Symposium on Lepton and Photon Interactions, Ithaca, NY, 10-15 Aug. 1993
(Contract DE-AC02-76CH-03000)
(DE93-019910; FNAL/C-93/205-E; CONF-930823-9) Avail: CASI HC A03/MF A01

If quarks are composite particles, then excited states are expected in p(bar-p) collisions. Using the CDF detector we have searched for excited quarks (q*) which decay to common quarks by emitting a W boson (q*

yields qW) or a photon (q* yields q(gamma)). In the W + jet and photon + jet mass spectra we see no compelling evidence for a q* mass resonance. We set an upper limit on the q* cross section vs. mass, and using the simplest model of excited quark production, we exclude excited quarks in the mass range 90 less than M* less than 570 GeV at 95% confidence level. This analysis is preliminary and only statistical uncertainties have been included. DOE

The charge asymmetry as a function of rapidity, A(y(sub l)), has been measured using the W decays to electrons and muons recorded by CDF during the 1992-93 run of the Tevatron Collider at Fermilab. The luminosity used, approximately 20 pb(sup -1), and detector improvements have lead to a six fold increase in statistics (in the plug region the increase is almost an order of magnitude) making discrimination between sets of parton distributions possible. Our data favors the most recent parton distributions and demonstrates the growing value of collider data in the measurement of the proton's structure. DOE

Measurements of the tensor analyzing power T(20) are in progress at the 2-GeV electron storage ring (VEPP-3) in Novosibirsk. Preliminary results from the second phase of this experiment will be presented along with a discussion of the theoretical implications of the existing data. Measurements of the (gamma)d yields pn reaction at photon energies above approximately 1 GeV were performed at SLAC during experiments NE8 and NE17. The results for experiment NE8 are final while those for NE17 are preliminary. The results appear to be consistent with the constituent scaling law near theta(sub CM) = 90 degrees, but inconsistent with the rule at a forward angle. DOE

DIRECT DETECTION OF ATOMIC IONS FROM MOLECULAR PHOTOFRAGMENTATION DURING NONRESONANT MULTIPHOTON IONIZATION OF SPUTTERED SPECIES
S. R. Coon, W. F. Calaway, M. J. Pellin, J. W. Burnett (Ames Lab., IA.), and J. M. White 1993 17 p
(Contract W-31-109-eng-38)
(DE93-040886; ANL/CHM/PP-79176) Avail: CASI HC A03/MF A01

The photoionization of sputtered Cu, Al, and Ru atoms and dimers was investigated by measuring velocity distributions using both resonant and nonresonant photoionization. Nonresonant ionization produced an atomic distribution that peaked at the same velocity as the respective dimer distribution, indicating that virtually all the nonresonant atomic ion signal is from photofragmented dimers. Various mechanisms of dimer photofragmentation are discussed. Domination of the atomic photoion channel by molecule fragmentation appears to be a general phenomenon that must be accounted for in all gas-phase multiphoton nonresonant ionization experiments at easily achievable laser power densities (less than or equal to 10(exp 9) W/cm(exp 2)). SYMMETRY-DICTATED TRUCATION: SOLUTIONS OF THE SPHERICAL SHELL MODEL FOR HEAVY NUCLEI
M. W. Guidry (Oak Ridge National Lab., TN.) 1992 18 p Presented at the Workshop on Nuclear Physics in the Universe, Oak Ridge, TN, 24-26 Sep. 1992
(Contracts DE-AC05-84OR-21400; DE-FG05-93ER-40770)
(DE94-000482; CONF-9209239-8) Avail: CASI HC A03/MF A01

Principles of dynamical symmetry are used to simplify the spherical shell model. The resulting symmetry-dictated truncation leads to dynamical symmetry solutions that are often in quantitative agreement with a variety of observables. Numerical calculations, including terms that break the dynamical symmetries, are shown that correspond to shell model calculations for heavy deformed nuclei. The effective residual interaction is simple, well-behaved, and can be determined from basic observables. With this approach, we intend to apply the shell model in systematic fashion to all nuclei. The implications for nuclear structure far from stability and for nuclear masses and other quantities of interest in astrophysics are discussed. DOE

INTERACTIONS OF SLOW H, H2, AND H3 WITH THIN FOILS
H. O. Funsten, B. L. Barraclough, and D. J. McComas 1993 12 p Presented at the ICACS 15th International Conference on Atomic Collision in Solids, London, Ontario, 26-30 Jul. 1993
(Contract W-7405-eng-36)

(DE93-040263; LA-UR-93-2790; CONF-930712-5) Avail: CASI HC A03/MF A01

Interaction processes resulting from the transit of incident 2-30 keV H(+), H2, and H3(+) through 1.2 to 2.5 mu-g/sq cm carbon foils are investigated by examining the charge state and angular scatter distributions of atomic and molecular species that exit the foils. A comparison of the scatter distributions of exiting H2(+) and H(0) show that H fragments from the same incident molecule that recombine to form H2 after transiting a foil scatter independently (i.e., not as a molecule) from foil atoms. The measured fractions of H2(+) from incident H2(+) and H3(+) are found to be dependent on the angular scatter half-width, but expected enhancements of this fraction for incident H3(+), due to the presence of an additional proton, are not observed within the experimental error. However, the observed fraction of H(0) is enhanced by approximately 2% for incident H2(+) and 4% for H3(+) relative to that observed using incident protons. This is evidence for a proximity effect at the exit surface of the foil in which the electron capture probability by one proton is enhanced by another proton in close proximity. DOE

PRODUCTION, COLLECTION AND UTILIZATION OF VERY LONG-LIVED HEAVY CHARGED LEPTONS

J. L. Goity, W. J. Kossler (College of William and Mary, Williamsburg, VA.), and M. Sher (College of William and Mary, Williamsburg, VA.) 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by poor print

(Contract DE-AC05-84ER-40150)

(DE93-040867; DOE/ER-40150/238; CEBAF-TH-93-07) Avail: Issuing Activity (Department of Energy (DOE))

If a fourth generation of leptons exists, both the neutrino and its charged partner must be heavier than 45 GeV. We suppose that the neutrino is the heavier of the two, and that a global or discrete symmetry prohibits intergenerational mixing. In that case, non-renormalizable Planck scale interactions will induce a very small mixing; dimension five interactions will lead to a lifetime for the heavy charged lepton of O(1-100) years. Production of such particles is discussed, and it is shown that a few thousands can be produced and collected at a linear collider. The possible uses of these heavy leptons is also briefly discussed. INELASTIC ELECTRON SCATTERING FROM SURFACES

1993 26 p

(Contract DE-FG02-84ER-45076)

(DE94-001738; DOE/ER-45076/3) Avail: CASI HC A03/MF A01

This program is aimed at the quantitative study of surface dynamical processes (vibrational, magnetic excitations) in crystalline slabs, ultrathin-layered materials, and chemisorbed systems on substrates, and of the geometric structure connected to these dynamical excitations. High resolution electron energy loss spectroscopy (HREELS) is a powerful probe. Off-specular excitation cross sections are much larger if electron energies are in the LEED range (50-300 eV). The analyses has been used to study surfaces of ordered alloys (NiAl). Ab-initio surface lattice dynamical results were combined with phonon-loss cross sections to achieve a more accurate microscopic description. First-principles phonon eigenvectors and eigenfrequencies were used as inputs to electron energy loss multiple scattering cross section calculations. The combined microscopic approach was used to analyze EELS data of Cu(0001) and Ag(001) at two points. Positron diffraction is discussed as a structural and imaging tool. Future research plans are presented. DOE

COMPUTER SIMULATION OF MOLECULAR RESPONSE AT A SHOCK FRONT

J. Belak Jul. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993

(Contract W-7405-eng-48)

(DE94-001050; UCRL-JC-113400; CONF-930676-60) Avail: CASI HC A02/MF A01

Molecular dynamics simulations of the response of small molecules at a shock front are presented. The simulations are performed in the reference frame of the shock and the results provide a unique insight into the sequence of states through which the material transforms during shock loading. The calculated up-pumping time (time for the translational and vibrational kinetic energy to equilibrate) for small molecules is quite fast, a few picoseconds for butane and about 10 ps for nitromethane. This is somewhat faster than the 100 ps suggested by a recent experiment. DOE

A MONTE CARLO STUDY OF THE SUDBURY NEUTRINO OBSERVATORY SMALL TEST DETECTOR EXPERIMENT M.S. Thesis

Alan B. Yeung 29 Jan. 1990 73 p

(ISBN-0-315-59056-4; CTN-94-60883) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A Monte Carlo study of the Sudbury Neutrino Observatory's small-scale prototype detector experiment is presented. This detector, called the Small Test Detector, consists of a cylindrical water-filled tank with 43 photomultiplier tubes arranged in a cylindrical array facing the center of the tank. Electrons are fired into the center of the tank at energies in the 2-11 MeV range and the responses of the photomultipliers are recorded for single electron events. The Monte Carlo simulation breaks down the electron's trajectory into small steps or cells; photons are simulated in a similar way to electrons. The modelling of the electromagnetic interactions that occur as a result of electrons entering the water (multiple scattering, bremsstrahlung, ionization energy loss, Cerenkov radiation, Compton scattering, and pair production by photons) is described. The simulated photoelectron yield as a function of incident electron energy, and the angular distributions of photomultiplier tube response for 3.0, 6.5, and 11.0 MeV electrons show excellent agreement with the experimental results. LIKELIHOOD ANALYSIS OF PARITY VIOLATION IN THE COMPOUND NUCLEUS

D. Bowman and E. Sharapov (Joint Inst. for Nuclear Research, Dubna, USSR.) 1993 11 p Presented at the International Workshop/Time Reversal Invariance and Parity Violation in Neutron Physics, Dubna, Russia, 4-7 May 1993

(Contract W-7405-eng-36)
(DE94-000671; LA-UR-93-3516; CONF-9305235-4) Avail: CASI HC A03/MF A01

We discuss the determination of the root mean-squared matrix element of the parity-violating interaction between compound-nuclear states using likelihood analysis. We briefly review the relevant features of the statistical model of the compound nucleus and the formalism of likelihood analysis. We then discuss the application of likelihood analysis to data on parity-violating longitudinal asymmetries. The reliability of the extracted value of the matrix element and errors assigned to the matrix element is stressed. We treat the situations where the spins of the p-wave resonances are not known and known using experimental data and Monte Carlo techniques. We conclude that likelihood analysis provides a reliable way to determine M and its confidence interval. We briefly discuss some problems associated with the normalization of the likelihood function. INELASTIC NEUTRON SCATTERING OF (GAMMA)-IRON, AND THE DETERMINATION OF THE ELASTIC CONSTANTS BY LATTICE DYNAMICS
C. Stassis 1993 4 p Presented at the 14th International Conference of the Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-82)
(DE94-000694; IS-M-765; CONF-930676-57) Avail: CASI HC A01/MF A01

The physical properties of the various phases of iron have been the subject of numerous theoretical and experimental investigations. Of particular interest is the appearance of the fcc (gamma)-phase between approximately 1,200 K and 1,670 K. The authors were able to grow in situ single crystals of fcc iron of sufficient size to perform an inelastic neutron scattering study of the lattice dynamics of this phase of iron. The phonon dispersion curves along the (00(xi)), ((xi)(xi)0) and ((xi)(xi)(xi)) symmetry directions were measured at 1,428 K. A limited number of phonons were also measured at 1,227 K and 1,640 K to assess the temperature dependence of the phonon frequencies. The data collected at 1,428 K were used to evaluate the elastic constants, the phonon density of states and the lattice contribution to the specific heat. The measured dispersion curves of (gamma)-Fe are qualitatively similar to those of Ni (measured at 296 K) and Ni(0.3)Fe(0.7) (measured at 296 and 573 K). DOE

METHOD TO EVALUATE STEERING AND ALIGNMENT ALGORITHMS FOR CONTROLLING EMITTANCE GROWTH
C. Adolphsen and T. Raubenheimer Apr. 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00515)
(DE93-041004; SLAC-PUB-6233; CONF-930511-436) Avail: CASI HC A01/MF A01

Future linear colliders will likely use sophisticated beam-based alignment and/or steering algorithms to control the growth of the beam emittance in the linac. In this paper, a mathematical framework is presented which simplifies the evaluation of the effectiveness of these algorithms. As an application, a quad alignment algorithm that uses beam data taken with the nominal linac optics, and with a scaled optics, is evaluated in terms of the dispersive emittance growth remaining after alignment. DOE

N94-19873# Stanford Linear Accelerator Center, CA.
A FIELD-BASED TECHNIQUE FOR THE LONGITUDINAL PROFILING OF ULTRARELATIVISTIC ELECTRON OR POSITRON BUNCHES DOWN TO LENGTHS OF LESS THAN OR EQUAL TO 10 MICRONS
R. Tatchyn May 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00515)
(DE93-040954; SLAC-PUB-6105; SLAC/SSRL-0019; CONF-930511-419)
Avail: CASI HC A01/MF A01

Present and future generations of particle accelerating and storage machines are expected to develop ever-decreasing electron/positron bunch lengths, down to 100 microns and beyond. A method for measuring the longitudinal profiles of ultrashort (1000 microns - 10 microns) bunches, based on: (1) the extreme field compaction attained by ultrarelativistic particles, and (2) the reduction of the group velocity of a visible light pulse in a suitably-chosen dielectric medium, is outlined. DOE

APERTURE DETERMINATION OF RHIC92 FROM RANDOMLY GENERATED INITIAL COORDINATES
G. F. Dell 1992 12 p Presented at the Workshop on the Stability of Particle Motion in Storage Rings, Upton, NY, 19-24 Oct. 1992
(Contract DE-AC02-76CH-00016)
(DE93-040174; BNL-49380; CONF-921077-13) Avail: CASI HC A03/MF A01

Results obtained by tracking 100 particles for 1,000 turns when initial coordinates are selected randomly, with the requirement that the total emittance be constant, are compared to results from 1,000-turn and 10(exp 6)-turn runs when initial coordinates satisfy epsilon(sub x)(i) = epsilon(sub y)(i) and X(sub i) prime = Y(sub i) prime = 0. For studies of ten distributions of magnetic field errors, the 100-particle results give apertures equivalent to those from 10(exp 6)-turn runs, have an aperture distribution of considerably less width, and yet require only one tenth the computer time. DOE

TOP SEARCH AT THE TEVATRON
Q. Li-Demarteau Jul. 1993 10 p Presented at the International Workshop on Physics and Instrumentation at Future Linear Colliders, Kona, HI, 26-30 Apr. 1993
(Contract DE-AC02-76CH-03000)
(DE93-019392; FNAL/C-93/223; CONF-930449-2) Avail: CASI HC A02/MF A01

Preliminary results on the top quark search at the TEVATRON are reported. The D(0) experiment, observing one candidate event in the e(mu) channel and combining the ee and e(mu) channel analyses, sets a lower limit of 103 GeV/sq c (99 GeV/sq c) for the top quark mass with (without) background subtraction at 95% confidence level. The CDF experiment, observing two candidate events, sets a top mass lower limit of 108 GeV/sq c at 95% confidence level for the ee, (mu)(mu) and e(mu) data combined, without background subtraction. Work is in progress at both experiments to reduce the backgrounds in the lepton + jets channel. DOE

STUDY OF TRANSVERSE COUPLED BUNCH INSTABILITIES BY USING NON-LINEAR TAYLOR MAPS FOR THE ADVANCED LIGHT SOURCE (ALS)
M. Meddahi and J. Bengtsson May 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-040287; LBL-33226; ESG-219; CONF-930511-398) Avail: CASI HC A01/MF A01

To study coherent bunch instabilities for the third generation light source, ALS, it is insufficient to rely on a linear map with radiation damping for the lattice to obtain the correct dynamics. We have implemented a code for transverse bunch instabilities using a 4-dimensional map for the lattice and wake field expansions for cavities and resistive wall effects. This model has been used to study the injection process and to determine the needed performance of the proposed feedback system for the storage ring. DOE

JET SHAPES IN HADRON AND ELECTRON COLLIDERS
N. Wainer May 1993 13 p Presented at the 1993 Rencontres de Physique de la Vallee d'Aoste, LaThuile, Italy, 8-13 Mar. 1993
(Contract DE-AC02-76CH-03000)
(DE93-019386; FNAL/C-93/122-E; CONF-9303172-3) Avail: CASI HC A03/MF A01

High energy jets are observed both in hadronic machines like the Tevatron and electron machines like LEP. These jets have an extended structure in phase space which can be measured. This distribution is usually called the jet shape. There is an intrinsic relation between jet variables, like energy and direction, the jet algorithm used, and the jet shape. Jet shape differences can be used to separate quark and gluon jets. DOE

HIGH CURRENT INJECTOR FOR HEAVY ION FUSION
S. Yu, S. Eylon, and W. W. Chupp May 1993 14 p Presented at the International Symposium on Heavy Ion Fusion, Frascati, Italy, 25-28 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019241; LBL-33806; HIFAN-585; CONF-9305136-9) Avail: CASI HC A03/MF A01

A 2 MV, 800 mA, K(+) injector for heavy ion fusion studies is under construction. This new injector is a one-beam version of the proposed 4-beam ILSE injector. A new 36-module MARX is being built to achieve a 5 micro-s flat top. The high voltage generator is stiff (less than 5k Omega) to minimize effects of beam-induced transients. A large (approximately 7 in. diameter) curved hot alumina-silicate source emits a 1 micro-s long beam pulse through a gridless extraction electrode, and the ions are

accelerated to 1 MV in a diode configuration. Acceleration to 2 MV takes place in a set of electrostatic quadrupole (ESQ) units, arranged to simultaneously focus and accelerate the ion beam. Heavy shields and other protection devices have been built in to minimize risks of high voltage breakdown. Beam aberration effects through the ESQ have been studied extensively with theory, simulations, and scaled experiments. The design, simulations, experiments, and engineering of the ESQ injector will be presented. DOE

N94-20290# California Univ., Berkeley. Lawrence Berkeley Lab.
LONGITUDINAL INSTABILITY OF AN INDUCTION LINAC WITH ACCELERATION
L. Smith and E. P. Lee May 1993 7 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019249; LBL-33288; HIFAN-573; CONF-930511-365) Avail: CASI HC A02/MF A01

The question arises as to what effect acceleration, which so far has been ignored, has on the longitudinal instability of an induction linac. The answer is not much for the anticipated acceleration rate (1-2 MeV/m) and minimum e-folding distance for the instability (50-500 m). However, total unstable growth is significantly reduced over distances which are long enough for appreciable acceleration to occur. The purpose of this note is to record a calculation of the instability including a constant acceleration rate. Some interesting features emerge--for example, the velocity of the head is a more convenient independent variable than axial position and, for an initial sinusoidal perturbation of velocity in time, the number of oscillations along the pulse is constant; however, as the pulse shortens in time the frequency increases. DOE

MEASUREMENT AND COMPUTATION OF THE HIGHER ORDER MODES OF THE ALS 500 MHz ACCELERATING CAVITIES
J. N. Corlett and J. M. Byrd May 1993 6 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019256; LBL-33278; ESG-233; CONF-930511-372) Avail: CASI HC A02/MF A01

Higher order modes in the accelerating cavities are expected to drive coupled bunch instabilities in the ALS, which will be overcome by a bunch-by-bunch feedback system. Computations of the cavity higher order modes using the URMEL-T and MAFIA codes are presented. Damping of the higher order modes is achieved by filters in the high power feeder waveguide which is aperture coupled to the cavity. Measurements of the modes in an ALS 500 MHz cavity are presented and compared with computed values for an isolated, un-damped cavity. The resources of the Lambertson Beam Electrodynamics Laboratory of the Center for Beam Physics at LBL were used to perform these studies. DOE

OBSERVATION OF REFLECTED WAVES ON THE SABRE POSITIVE POLARITY INDUCTIVE ADDER MITL
M. E. Cuneo, J. W. Poukey, C. W. Mendel, S. E. Rosenthal, D. L. Hanson, J. R. Smith, J. E. Maenchen, D. F. Wenger, and M. A. Bernard 1993 5 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019413; SAND-92-2812C; CONF-930616-30) Avail: CASI HC A01/MF A01

We are studying the coupling of extraction applied-B ion diodes to Magnetically Insulated Transmission Lines (MITL's) on the SABRE (Sandia Accelerator and Beam Research Experiment, 6 MV, 300 kA) positive polarity inductive voltage adder. Our goal is to determine the conditions under which efficient coupling occurs. The best total power efficiency for an ideal ion diode load (i.e., without parasitic losses) is obtained by maximizing the product of cathode current and gap voltage. MITL's require that the load impedance be undermatched to the self-limited line operatingimpedance for efficient transfer of power to ion diodes, independent of transit time isolation, and even in the case of multiple cathode system with significant vacuum electron flow. We observe that this undermatched condition results in a reflected wave which decreases the line voltage and gap electron sheath current, and increases the anode and cathode current in a time-dependent way. The MITL diode coupling is determined by the flow impedance at the adder exit. We also show that the flow impedance increases along the extension MITL on SABRE. Experimental measurements of current and peak voltage are compared to analytical models and TWOQUICK 2.5-D PIC code simulations. DOE

N94-20300# Lawrence Livermore National Lab., CA.
ENERGY AND LUMINOSITY LIMITS OF HADRON SUPERCOLLIDERS
W. A. Barletta May 1993 6 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019248; LBL-34068; CONF-930511-377) Avail: CASI HC A02/MF A01

Extending the frontiers of experimental high energy physics in a manner that maximizes discovery potential requires the building of accelerators of ever higher particle energies and luminosities. Both hadron and e(+)e(-) colliders have been proposed for this role. Based on a self-consistent computational model, this paper explores the features of hadron supercolliders beyond the SSC. The application of the presently available accelerator technologies embodied in the designs of the LHC and SSC to an ELOISATRON operating at 100 TeV per beam would yield a collider with a luminosity of 10(exp 34) cm(exp -2) s(exp -1). Even higher energies and luminosities are clearly possible. The paper concludes with an examination of the ultimate potential of synchrontron-based colliders to explore PeV energies. DOE

ELECTRON QUANTUM YIELDS FROM A BARIUM PHOTOCATHODE ILLUMINATED WITH POLARIZED LIGHT
M. E. Conde, S. Chattopadhyay, K. J. Kim, S. I. Kwon, K. N. Leung, and A. T. Young May 1993 5 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019232; LBL-33303; ESG-236; CONF-930511-376) Avail: CASI HC A01/MF A01

Photoemission measurements with a barium photocathode and a nitrogen laser are reported. The cathode is prepared by evaporating barium onto a copper disc. Radiation from a nitrogen laser (337 nm, 10 ns) is polarized and strikes the cathode surface at variable angles. An electron quantum yield as high as 1 x 10(sup -3) is observed. The dependence of the quantum yield on the beam polarization and angle of incidence is investigated. The results indicate that higher quantum yields are achieved when the laser beam is incident at an angle of approximately 55 degrees and is polarized perpendicular to the plane of incidence. DOE

LOW EMITTANCE 0.8A K(+) ION SOURCE FOR THE LBL INDUCTION LINAC SYSTEM EXPERIMENT (ILSE)
S. Eylon, E. Henestroza, W. W. Chupp, and S. Yu May 1993 14 p Presented at the International Symposium on Heavy Ion Fusion, Frascati, Italy, 25-28 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019237; LBL-33802; HIFAN-581; CONF-9305136-6) Avail: CASI HC A03/MF A01

A high current injector for heavy ion fusion presently under construction at Lawrence Berkeley Laboratory requires large sources of up to 17 cm in diameter and total potassium ion current of 790 mA with a low normalized transverse emittance of less than 0.5 mm-mr. A 1 in. diameter hot alumina silicate (zeolite) source was fabricated and tested in the injector setup of SBTE, an existing facility at LBL. Initial measurements showed a maximum space charge limited ion current of 95 mA. The corresponding density of 19 mA/sq cm was limited by the source diode optics and not by the source emission. The density required for the high current injector is 4 mA/sq cm. The normalized emittance was measured to be 0.06 mm-mrad, corresponding to a transverse temperature of 0.2 eV. Non-destructive life tests showed that the source can be operated under continuous operating conditions of the high current injector for more than a month (twenty eight-hour days, with 1 micro-s long pulses at 1 Hz). D.C. destructive life tests showed that approximately 30% of the total stored K can be ionized and extracted, allowing, in principle, for years of operation for the high current injector. Furthermore, we shall describe the extension of the fabricating technique to large diameter sources (up to 17 cm) and report on measured ion emission performance, measured surface temperature uniformity and heating power considerations. DOE

SIMULATION STUDIES OF SPACE-CHARGE-DOMINATED BEAM TRANSPORT IN LARGE APERTURE RATIO QUADRUPOLES
W. M. Fawley, L. J. Laslett, C. M. Celata, A. Faltens, and I. Haber (Naval Research Lab., Washington, DC.) May 1993 6 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contracts DE-AC03-76SF-00098; DE-AI05-92ER-54177)
(DE93-019238; LBL-33282; HIFAN-566; CONF-930511-363) Avail: CASI HC A02/MF A01

For many cases of interest in the design of heavy-ion fusion accelerators, the maximum transportable current in a magnetic quadrupole lattice scales as alpha/L(sup 2) where alpha is the useful dynamic aperture and L is the half-lattice period. There are many cost benefits to maximizing the usable aperture which must be balanced against unwanted effects such as possible emittance growth and particle loss from anharmonic fringe fields. We have used two independent simulation codes to model space-charge dominated beam transport both in an azimuthally-pure quadrupole FODO lattice design and in a more conventional design. Our results indicate that careful matching will be necessary to minimize emittance growth and that (alpha/L) ratios of 0.2 or larger are possible for particular parameters. DOE

N94-21686# Stanford Linear Accelerator Center, CA.
MULTIBUNCH BEAM BREAK-UP IN DETUNED STRUCTURES
K. A. Thompson, C. Adolphsen, and K. L. F. Bane May 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00515)
(DE93-041056; SU-SLAC-Pub-6153; CONF-930511-478) Avail: CASI HC A01/MF A01

A key problem in next-generation linear collider design utilizing multibunching is the control of multibunch beam break-up. One method of controlling the break-up is detuning, i.e., varying the frequency of the transverse deflecting modes by varying the cell dimensions within the accelerating structures. In this case, the beam breakup is sensitive to the resonances between the bunch frequency and some of the deflecting mode frequencies. It is also sensitive to errors in the fabrication and alignment of the accelerating structures. We examine these effects in the context of the SLAC NLC design. DOE

The SLAC NLC design for a next-generation linear collider utilizes multibunching (acceleration of a train of bunches on each RF fill) to increase the luminosity and energy efficiency. It is necessary to control the energy spread of the beam, in order to minimize chromatic emittance dilution and be within the energy acceptance of the final focus. It is anticipated that the NLC may run with bunch trains having length equal to a substantial fraction of the filling time. Multibunch energy simulation methods and compensation schemes appropriate to this regime are presented. DOE

PLASMA LENS EXPERIMENTS AT THE FINAL FOCUS TEST BEAM
B. Barletta, S. Chattopadhyay (California Univ., Berkeley. Lawrence Berkeley Lab.), P. Chen (Stanford Linear Accelerator Center, CA.), D. Cline, W. Craddock (Stanford Linear Accelerator Center, CA.), W. Gabella (Stanford Linear Accelerator Center, CA.), I. Hsu (National Tsing Hua Univ., Hsinchu, Taiwan.), T. Katsouleas (University of Southern California, Los Angeles.), P. Kwok, and P. Lau (University of Southern California, Los Angeles.) et al Apr. 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00515)
(DE93-041081; SU-SLAC-Pub-6195; CONF-930511-432) Avail: CASI HC A01/MF A01

We intend to carry out a series of plasma lens experiments at the Final Focus Test Beam facility at SLAC. These experiments will be the first to study the focusing of particle beams by plasma focusing devices in the parameter regime of interest for high energy colliders, and is expected to lead to plasma lens designs capable of unprecedented spot sizes. Plasma focusing of positron beams will be attempted for the first time. We will study the effects of lens aberrations due to various lens imperfections. Several approaches will be applied to create the plasma required including laser ionization and beam ionization of a working gas. At an increased bunch population of 2.5 x 10(exp 10), tunneling ionization of a gas target by an electron beam -- an effect which has never been observed before -- should be significant. The compactness of our device should prove to be of interest for applications at the SLC and the next generation linear colliders. DOE

A HIGH-INTENSITY He-JET PRODUCTION SOURCE FOR RADIOACTIVE BEAMS
D. J. Vieira, H. J. Kimberly, D. L. Grisham, W. L. Talbert, J. M. Wouters, D. Rosenauer, and Y. Bai 1993 6 p Presented at the 3rd International Conference on Radioactive Nuclear Beams, East Lansing, MI, 24-27 May 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE93-040247; LA-UR-93-2759; CONF-930534-7) Avail: CASI HC A02

The use of a thin-target, He-jet transport system operating with high primary beam intensities is explored as a high-intensity production source for radioactive beams. This method is expected to work well for short-lived, non-volatile species. As such, the thin-target, He-jet approach represents a natural complement to the thick-target ISOL method in which such species are not, in general, rapidly released. Highlighted here is a thin-target, He-jet system that is being prepared for a 500(+) micro-A, 800-MeV proton demonstration experiment at LAMPF this summer. DOE

(DE93-040964; SU-SLAC-PUB-6117; CONF-930511-406) Avail: CASI HC A01

Many future linear collider designs require beams with very small transverse emittances and large emittance ratios epsilon(sub x) (much greater than) epsilon(sub y). In this paper, we will discuss issues associated with the preservation of these small emittances during the acceleration of the beams. The primary sources of transverse emittance dilution in a high energy linear accelerator are the transverse wakefields, the dispersive errors, RF deflections, and betatron coupling. We will discuss the estimation of these effects and the calculation of tolerances that will limit the emittance dilution with a high degree of confidence. Since the six-dimensional emittance is conserved and only the projected emittances are increased, these dilutions can be corrected if the beam has not filamented (phase mixed). We discuss methods of correcting the dilutions and easing the tolerances with beam-based alignment and steering techniques, and non-local trajectory bumps. Finally, we discuss another important source of luminosity degradation; namely, pulse-to-pulse jitter. DOE

LOW p(SUB T) PHENOMENA OBSERVED IN HIGH ENERGY NUCLEAR COLLISIONS
J. Simon-Gillo 1993 9 p Presented at the 10th International Conference on Ultra-Relativistic Nucleus-Nucleus Collisions, Borlaenge, Sweden, 20-24 Jun. 1993
(Contract W-7405-eng-36)
(DE94-000825; LA-UR-93-3429; CONF-930636-3) Avail: CASI HC A02/MF A01

For several decades, experiments have reported an enhancement in the pion invariant cross section at low p(sub T) (less than 300 MeV/c) when compared to a thermal fit or minimum bias pp results. Experimental results from pp reactions at the ISR to heavy ion collisions at CERN will be reviewed then compared to extract trends. Several theoretical explanations will be discussed. An emphasis will be placed on the role of resonances, and a comparison of data to models will be presented. DOE

MEASUREMENT OF THE INCLUSIVE JET CROSS SECTION IN p(BAR-p) COLLISIONS AT CDF
Aug. 1993 10 p Presented at the Symposium on Lepton and Photon Interactions, Ithaca, NY, 10-15 Aug. 1993
(Contract DE-AC02-76CH-03000)
(DE94-000581; FNAL/C-93/204-E; CONF-930823-11) Avail: CASI HC A02/MF A01

The status of the CDF inclusive jet cross section measurement from the 1992-1993 run of the Fermilab Tevatron is described. The E(sub T) range of the jets extends from 15 to 420 GeV. Corrections are made to the measured cross section to obtain a true transverse energy spectrum. The corrected cross section is compared with next-to-leading order (NLO) quantum chromodynamics (QCD) calculations and to the 1989 CDF data. DOE

The principal activity during the past six months has involved the analysis of ion cyclotron waves recorded from DE-2 using the magnetic field experiment and electric field experiment. The results of this study have been published in the Geophysical Research Letters (GRL). The primary finding of this paper is that ion cyclotron waves were found to heat electrons, as observed in the DE-2 Langmuir probe data, through a Landau damping process. A second activity, which was started during the last six months, involves the study of large amplitude approximately one Hz electric and magnetic field oscillations recorded in the nightside auroral zone at substorm onset. Work is under way to determine the properties of these waves and investigate any association these waves may have with the substorm initiation process. A third activity under way involves a comprehensive study of ion cyclotron waves recorded at ionospheric altitudes by DE-2. This study will be an extension of the work reported in the GRL paper and will involve a larger sampling of wave events. This paper will focus on wave properties at ionospheric altitudes. A fourth activity involves a more in-depth analysis of the acceleration mechanisms and the resulting electron distributions based on the observations presented in the GRL paper. Derived from text

STABILITY OF BEAM IN THE FERMILAB MAIN INJECTOR
C. S. Mishra and F. A. Harfoush Aug. 1993 5 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC02-76CH-03000)
(DE94-000619; FNAL/C-93/229; CONF-930511-489) Avail: CASI HC A01/MF A01

The Fermilab Main Injector is a new 150 GeV protron synchrotron, designed to remove the limitations of the Main Ring in the delivery of high intensity protron and antiproton beams to the Tevatron. Extensive studies have been made to understand the performance of the Main Injector. In this paper, we present a study of the Main Injector lattice, which includes magnetic and misalignment errors. These calculations show the Main Injector's dynamical aperture is larger than its design value of 40 pi mm mradian at injection. DOE

MONTE CARLO CALCULATION OF MULTI-ELECTRON EFFECTS ON SYNCHROTRON RADIATION
C. Wang Jul. 1993 12 p Presented at the Annual Meeting of the SPIE, San Diego, CA, 11-16 Jul. 1993
(Contract DE-AC03-76SF-00098)
(DE94-001259; LBL-33355; CONF-930722-44) Avail: CASI HC A03/MF A01

The phase space distribution and time structure of an electron beam have fundamental influences on synchrotron radiation properties. These influences are due to the superposition of radiation from all electrons, each following a different trajectory. When the radiation wavelength is longer than the electron bunch length, coherent superposition occurs and results in the observed coherent synchrotron radiation. Usually the wavelength we use is much shorter, so incoherent superposition occurs and the emittance effect is the dominant multi-electron effect. The Monte Carlo simulation is a straightforward and generally valid approach to compute the multi-electron effects on synchrotron radiation. In this paper, we show how the Monte Carlo method can model these multi-electron effects systematically and discuss the statistical principles governing such simulation and their implication on the computing power requirement. We also describe the implementation of an efficient algorithm to calculate a single electron radiation spectrum, which is important to make the Monte Carlo simulation practical. Some calculated results are shown to demonstrate the methods. Comments on the usefulness and limitation of the Monte Carlo method are presented. DOE

RECOGNIZING 3-D OBJECTS USING 2-D IMAGES
David W. Jacobs May 1993 272 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-91-J-4038; N00014-85-K-0124)
(AD-A271005; AI-TR-1416) Avail: CASI HC A12

To visually recognize objects, the strategy of forming groups of image features with a bottom-up process, and then using these groups to index into a data base to find all of the matching groups of model features is adopted. This approach reduces the computation needed for recognition, since we only consider groups of model features that can account for these relatively large chunks of the image. To perform indexing, a group of 3-D model features are represented in terms of the 2-D images it can produce. Specifically, it is shown that the simplest and most space-efficient way of doing this for models consisting of general groups of 3-D point features is to represent the set of images each model group produces with two lines (1D subspaces), one in each of two orthogonal, high-dimensional spaces. These spaces represent all possible image groups so that a single image group corresponds to one point in each space. The effects of bounded sensing error on a set of image points, so that a robust and efficient indexing system may be built are determined. An optimal indexing method for more complicated features is also presented, and bounds on the space required for indexing in a variety of situations is presented. The representations of a model's images that are developed to analyze other approaches to matching were used. It is shown that there are no invariants of general 3-D models, and limitations in the use of non-accidental properties and in other approaches to reconstructing a 3-D scene from a single 2-D image are demonstrated. This Phase 1 research program resulted in the synthesis and identification of a previously unknown set of aromatic phosphonic acid compounds, which possessed interesting thermal properties. There are very few phosphonate compounds reported that are liquid crystalline in nature. However, the non-linear optical properties of these compounds were determined to be unremarkable. Very probably, this is due to a relatively small dipole between the phosphonate moiety and a distal cyano group. DTIC

(DE93-019923; UCRL-JC-114989; CONF-931057-1) Avail: CASI HC A03/MF A01

We demonstrate that nonlinear optical fiber arrays can support stable soliton-like pulses with finite energy. The bound state that we have found is localized both in time and in a spatial domain in the direction perpendicular to the pulse propagation. We have proved the boundedness of the Hamiltonian function for the array. Finally, numerical studies support our analytical conclusions. DOE

In order to explore the existence of spontaneous self-organization of states in quantum optics on a more concrete basis and to learn from known examples of many-body systems that show self-organization, we have taken up the study of Heisenberg Ferromagnetism. This is the magnetism of spherically symmetric spins interacting via the exchange Hamiltonian on two or three dimensional lattices. We have extracted the essential elements necessary for self-locking and the ensuing metastability of the system in the absence of any external field. Since the functional space of the Heisenberg ferromagnetic spins is homomorphic to the space of two level atoms, our recent results in magnetism will allow us to pass with great ease to the quantum optics case of self-locked bistable states and demonstrate their existence on a first-principles basis. ON GEOMETRIC AND ALGEBRAIC ASPECTS OF 3D AFFINE AND PROJECTIVE STRUCTURES FROM PERSPECTIVE 2D VIEWS Memorandum Report
Amnon Shashua Jul. 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-91-J-1270; N00014-92-J-1879)
(AD-A270520; AIM-1405; CBCI-78) Avail: CASI HC A03

Part I of this paper investigates the differences conceptually and algorithmically - between affine and projective frameworks for the tasks of visual recognition and reconstruction from perspective views. It is shown that an affine invariant exists between any view and a fixed view chosen as a reference view. This implies that for tasks for which a reference view can be chosen, such as in alignment schemes for visual recognition, projective invariants are not really necessary. The projective extension is then derived, showing that it is necessary only for tasks for which a reference view is not available - such as happens when updating scene structure from a moving stereo rig. The geometric difference between the two proposed invariants are that the affine invariant measures the relative deviation from a single reference plane, whereas the projective invariant measures the relative deviation from two reference planes. The affine invariant can be computed from three corresponding points and a fourth point for setting a scale; the projective invariant can be computed from four corresponding points and a fifth point for setting a scale. Both the affine and projective invariants are shown to be recovered by remarkably simple and linear methods. DTIC

OPTICAL SIGNAL PROCESSING Final Report, 5 Feb. 1990 - 30 Jun. 1993
A. VanderLugt 31 Jul. 1993 193 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-90-G-0039)
(AD-A271036; ARO-27586.21-PH) Avail: CASI HC A09

A quasi-realtime adaptive processing system was used to correct the multipath distortion found in wideband digital radios. The measured power spectral density of the input signal was used to adaptively select one of eight equalization filters which reduce the residual distortion to less than 3.6 dB even for the most severe channel distortion. A related adaptive system was used for signal excision in which we removed narrowband interference from wideband signals with minimum signal distortion. An 8x8 acousto-optic switch in a multimode fiber-optic system was built. Insertion loss is approximately 2-4 dB, signal-to-crosstalk ratio is better than 25 dB, and the reconfiguration time is 880 nsec. Short pulses were detected by using the Fresnel transform. Pulses as short as the theoretical limit of 20 nanoseconds were detected for this system, and separated by as little as 60 nanoseconds or by as much as 17 nanoseconds. All possible acousto-optic scanning configurations were considered and classified into four basic types. A consistent set of design relationships for each of the scanning configurations was developed and presented in both tabular and graphic forms from which a preliminary design is obtained. DTIC

FIBER OPTIC MICHELSON SENSOR AND ARRAYS WITH PASSIVE ELIMINATION OF POLARIZATION FADING AND SOURCE FEEDBACK ISOLATION Patent
Alan D. Kersey, inventor (to Navy) 27 Apr. 1993 15 p Filed 1 Sep. 1992
(AD-D015944; US-Patent-5,206,924; US-Patent-Appl-SN-937782; US-Patent-Class-385-24) Avail: US Patent and Trademark Office

A fiber optic Michelson interferometric sensor system with passive elimination of polarization fading and source feedback isolation is disclosed. In a preferred embodiment, an optical source provides light of a first polarization state to a polarization selective element. Output light from the polarization selective element passes through a length of optical fiber into a Michelson interferometric sensor which utilizes a Faraday rotator/mirror assembly, that is coupled to distal ends of sensing and reference arms of the Michelson interferometer, to provide for the passive elimination of polarization fading. The polarization selective element at the output of the optical source provides isolation of the optical source from the Michelson interferometer sensor. DTIC

X RAY, EXTREME AND FAR ULTRAVIOLET OPTICAL THIN FILMS FOR SPACE APPLICATIONS
Muamer Zukic, Douglas G. Torr, and Jongmin Kim 1993 41 p
(Grant NAGw-2898)
(NASA-CR-194635; NAS 1.26:194635) Avail: CASI HC A03/MF A01

Far and extreme ultraviolet optical thin film filters find many uses in space astronomy, space astrophysics, and space aeronomy. Spacebased spectrographs are used for studying emission and absorption features of the earth, planets, sun, stars, and the interstellar medium. Most of these spectrographs use transmission or reflection filters. This requirement has prompted a search for selective filtering coatings with high throughput in the FUV and EUV spectral region. Important progress toward the development of thin film filters with improved efficiency and stability has been made in recent years. The goal for this field is the minimization of absorption to get high throughput and enhancement of wavelength selection. The Optical Aeronomy Laboratory (OAL) at the University of Alabama in Huntsville has recently developed the technology to determine optical constants of bulk and film materials for wavelengths extending from x-rays (0.1 nm) to the FUV (200 nm), and several materials have been identified that were used for designs of various optical devices which previously have been restricted to space application in the visible and near infrared. A new design concept called the Pi-multilayer was introduced and applied to the design of optical coatings for wavelengths extending from x-rays to the FUV. Section 3 of this report explains the Pi-multilayer approach and demonstrates its application for the design and fabrication of the FUV coatings. Two layer Pi-stacks have been utilized for the design of reflection filters in the EUV wavelength range from 70 - 100 nm. In order to eliminate losses due to the low reflection of the imaging optics and increase throughput and out-of-band rejection of the EUV instrumentation we introduced a self-filtering camera concept. In the FUV region, MgF2 and LiF crystals are known to be birefringent. Transmission polarizers and quarterwave retarders made of MgF2 or LiF crystals are commercially available but the performances are poor. New techniques for the design of the EUV and FUV polarizers and quarterwave retarders are described in Section 5. X- and gamma-ray detectors rely on a measurement of the electron which is effected when a ray interacts with matter. The design of an x- and gamma-ray telescope to operate in a particular region of the spectrum is, therefore, largely dictated by the mechanism through which the rays interact. Energy selection and the focusing of the incident high energy rays can be achieved with spectrally selective high reflective multilayers. The design and spectral performance of narrowband reflective x-ray Pi-multilayers are presented in section 6. Derived from text

SOLAR SIMULATOR FOR SOLAR DYNAMIC SPACE POWER SYSTEM TESTING
Kent S. Jefferies Nov. 1993 8 p Proposed for presentation at the 1994 ASME International Solar Energy Conference, San Francisco, CA, 27-30 Mar. 1994; sponsored by ASME
(RTOP 585-03-21)
(NASA-TM-106393; E-8218; NAS 1.15:106393) Avail: CASI HC A02/MF A01

Planned vacuum tank testing of a solar dynamic space power system requires a solar simulator. Several solar simulators were previously built and used for vacuum tank testing of various space systems. However, the apparent solar subtense angle, i.e., the angular size of the apparent sun as viewed from the experiment, of these solar simulators is too large to enable testing of solar dynamic systems. A new design was developed to satisfy the requirements of the solar dynamic testing. This design provides 1.8 kW/m(sup 2) onto a 4.5M diameter test area from a source that subtends only 1 deg, full cone angle. Key features that enable this improved performance are (1) elimination of the collimating mirror commonly used in solar simulators to transform the diverging beam into a parallel beam; (2) a redesigned lamp module that has increased efficiency; and (3) the use of a segmented reflective surface to combine beams from several individual lamp modules at the pseudosun. Each segment of this reflective surface has complex curvature to control the distribution of light. By developing a new solar simulator design for testing of the solar dynamic system instead of modifying current designs, the initial cost was cut in half, the efficiency was increased by 50 percent reducing the operating costs by one-third, and the volume occupied by the solar simulator was reduced by a factor of 10. Author (revised)

DESIGN CONSIDERATIONS FOR A FIBER OPTIC COMMUNICATIONS NETWORK FOR POWER SYSTEMS
H. Kirkham, A. R. Johnston, and G. D. Allen (American Electric Power Service Corp., Columbus, OH.) 1993 8 p Presented at the IEEE Power Engineering Society Winter Meeting, Columbus, OH, 31 Jan. - 4 Feb. 1993
(Contract DE-AI05-79ET-29372)
(DE93-018404; CONF-930102-1) Avail: CASI HC A02/MF A01

The design of a fiber optic communication network for monitoring and control in power systems is discussed. It is shown that by appropriate choice of protocols, a fault-tolerant system can be built that operates in any arbitrary configuration. Since the network is based on fiber optics, it can be made fast enough for substation monitoring and control. In this application, a relatively small number of cables is required to implement a high reliability system. The network can also be used for distribution automation. In this application the network is required to reach all parts of the power system, and the fiber cable itself becomes a significant fraction of the cost of communications. However, since many applications can be supported at once, the cost per function can be reasonable. DOE

ROTARY ENCODING DEVICE USING POLYGONAL MIRROR WITH DIFFRACTION GRATINGS ON EACH FACET Patent
Douglas B. Leviton, inventor (to NASA) 30 Nov. 1993 13 p Filed 3 Nov. 1992 Supersedes N94-15705 (32 - 3, p 1189)
(NASA-Case-GSC-13543-1; US-Patent-5,266,796;
US-Patent-Appl-SN-971035; US-Patent-Class-250-231.18;
US-Patent-Class-250-237G; Int-Patent-Class-G01D-5/34) Avail: US Patent and Trademark Office

A device for position encoding of a rotating shaft in which a polygonal mirror having a number of facets is mounted to the shaft and a monochromatic light beam is directed towards the facets. The facets of the polygonal mirror each have a low line density diffraction grating to diffract the monochromatic light beam into a number of diffracted light beams such that a number of light spots are created on a linear array detector. An analog-to-digital converter is connected to the linear array detector for reading the position of the spots on the linear array detector means. A microprocessor with memory is connected to the analog-to-digital converter to hold and manipulate the data provided by the analog-to-digital converter on the position of the spots and to compute the position of the shaft based upon the data from the analog-to-digital converter.

OPTICS SURVIVABILITY SUPPORT, VOLUME 1
N. Wild, T. Simpson, A. Busdeker, and F. Doft Mar. 1993 86 p Prepared for Lawrence Livermore National Lab.
(Contract W-7405-eng-48)
(DE93-019616; UCRL-CR-114992-Vol-1) Avail: CASI HC A05/MF A01

This final report is a documentation of the activities and work performed by JAYCOR during the period from June 11, 1992 through March 10, 1993 to support Lawrence Livermore National Laboratory (LLNL) in the development of radiation tolerant optical subsystems and components for use under the Advanced Implementation Technology (AIT) effort. The work is primarily directed towards: performance of above-ground testing and analysis of the LLNL space-based LIDAR (Laser Illuminated Detection and Ranging) system and components, and compilation of a radiation effects data base for bulk optical materials, i.e., glasses. The objective is to support LLNL activities in the area of optics survivability and in engineering a radiation hardened LIDAR that can survive and operate through natural, as well as hostile, space environments (primary emphasis is on operation in electron, proton, and total dose environment). An analysis of the LIDAR design as developed by Kigre, Inc. for LLNL shows that the most susceptible components in terms of radiation susceptibility are the doubling crystal and laser rod materials. The radiation susceptibility analysis of the Kigre design (pulsed Q-switch mode) is performed using data obtained from above-ground testing of each individual component material. A passive Q-switch material is evaluated and found to degrade via a decrease in the amount of saturable absorption relative to an un-irradiated sample. Several different doubling crystal types (LBO, KTP, KD*P) are also evaluated for both total dose and high energy proton susceptibility. LBO is the least susceptible and KTP is the most affected by exposure to ionizing radiation. An analysis of the Kigre system response as a function of total dose is made, including the effects on thin film anti-reflection and band-pass filter coatings. DOE

(DE93-040310; J-204-93-0052/2789-Vol-2; UCRL-CR-114992-Vol-2) Avail: CASI HC A09/MF A03

This volume of the Optics Survivability Support Final Report contains plots of all the data contained in the computerized Optical Glasses Database. All of these plots are accessible through the Database, but are included here as a convenient reference. The first three pages summarize the types of glass included with a description of the radiation source, test date, and the original data reference. This information is included in the database as a macro button labeled 'LLNL DATABASE'. Following this summary is an Abbe chart showing which glasses are included and where they lie as a function of nu(sub d) and n(sub d). This chart is also callable through the database as a macro button labeled 'ABBEC'. DOE

An associative optical memory including an input spatial light modulator (SLM) in the form of an edge enhanced liquid crystal light valve (LCLV) and a pair of memory SLM's in the form of liquid crystal televisions (LCTV's) forms a matrix array of an input image which is cross correlated with a matrix array of stored images. The correlation product is detected and nonlinearly amplified to illuminate a replica of the stored image array to select the stored image correlating with the input image. The LCLV is edge enhanced by reducing the bias frequency and voltage and rotating its orientation. The edge enhancement and nonlinearity of the photodetection improves the orthogonality of the stored image. The illumination of the replicate stored image provides a clean stored image, uncontaminated by the image comparison process.

The sensitivity model of a complex optical system obtained by linear ray tracing is used to compute a control gain matrix by imposing the mathematical condition for minimizing the total wavefront error at the optical system's exit pupil. The most recent deformations or error states of the controlled segments or optical surfaces of the system are then assembled as an error vector, and the error vector is transformed by the control gain matrix to produce the exact control variables which will minimize the total wavefront error at the exit pupil of the optical system. These exact control variables are then applied to the actuators controlling the various optical surfaces in the system causing the immediate reduction in total wavefront error observed at the exit pupil of the optical system.

WIDE-ANGLE IMAGING SYSTEM WITH FIBEROPTIC COMPONENTS PROVIDING ANGLE-DEPENDENT VIRTUAL MATERIAL STOPS Patent

Arthur H. Vaughan, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 30 Nov. 1993 16 p Filed 1 Nov. 1991 Supersedes N92-17892 (30 - 8, p 1368)

(NASA-Case-NPO-18146-1-CU; US-Patent-5,266,795; US-Patent-Appl-SN-786618; US-Patent-Class-250-227.2; US-Patent-Class-359-896; Int-Patent-Class-H01J-5/16) Avail: US Patent and Trademark Office

A strip imaging wide angle optical system is provided. The optical system is provided with a 'virtual' material stop to avoid aberrational effects inherent in wide angle optical systems. The optical system includes a spherical mirror section for receiving light from a 180 deg strip or arc of a target image. Light received by the spherical mirror section is reflected to a frustoconical mirror section for subsequent rereflection to a row of optical fibers. Each optical fiber transmits a portion of the received light to a detector. The optical system exploits the narrow cone of acceptance associated with optical fibers to substantially eliminate vignetting effects inherent in wide angle systems. Further, the optical system exploits the narrow cone of acceptance of the optical fibers to substantially limit spherical aberration. The optical system is ideally suited for any application wherein a 180 deg strip image need be detected, and is particularly well adapted for use in hostile environments such as in planetary exploration.

OPTICAL FIBERS AND FLUOROSENSORS HAVING IMPROVED POWER EFFICIENCY AND METHODS OF PRODUCING SAME Patent

Claudio O. Egalon, inventor (to NASA) and Robert S. Rogowski, inventor (to NASA) 16 Nov. 1993 8 p Filed 16 Sep. 1991 Supersedes N93-22008 (31 - 7, p 2069)

(NASA-Case-LAR-14525-1-CU; US-Patent-5,262,638; US-Patent-Appl-SN-761198; US-Patent-Class-250-227.14; US-Patent-Class-385-12; Int-Patent-Class-G01N-21/00) Avail: US Patent and Trademark Office

Optical fibers may have applications including fluorosensors which sense the concentration of an analyte. Like communication fibers, these fluorosensors are modeled using a weakly guiding approximation which is only effective when the difference between the respective refractive indices of the fiber core and surrounding cladding are minimal. An optical fiber fluorosensor is provided having a portion of a fiber core which is surrounded by an active cladding which is permeable by the analyte to be sensed and containing substances which emit light waves upon excitation. A remaining portion of the fiber core is surrounded by a guide cladding which guides these light waves to a sensor which detects the intensity of waves, which is a function of the analyte concentration. Contrary to conventional weakly guiding principles, the difference between the respective indices of refraction of the fiber core is surrounded by an active cladding which is thin enough such that its index of refraction is effectively that of the surrounding atmosphere, thereby the atmosphere guides the injective indices of the fiber core and the cladding results in an unexpected increase in the power efficiency of the fiber core.

OPTICAL FIBER SENSOR HAVING AN ACTIVE CORE Patent

Claudio Oliveira Egalon, inventor (to NASA) and Robert S. Rogowski, inventor (to NASA) 28 Sep. 1993 10 p Filed 18 Mar. 1992 Supersedes N92-30029 (30 - 20, p 3553) Continuation-in-part of US-Patent-Appl-SN-761198, filed 16 Sep. 1991

(NASA-Case-LAR-14607-1-SB; US-Patent-5,249,251; US-Patent-Appl-SN-855363; US-Patent-Appl-SN-761198; US-Patent-Class-385-123; US-Patent-Class-385-126; US-Patent-Class-385-127; US-Patent-Class-385-128; US-Patent-Class-385-142; US-Patent-Class-372-6) Avail: US Patent and Trademark Office

An optical fiber is provided. The fiber is comprised of an active fiber core which produces waves of light upon excitation. A factor ka is identified and increased until a desired improvement in power efficiency is obtained. The variable a is the radius of the active fiber core and k is defined as 2 pi/lambda wherein lambda is the wavelength of the light produced by the active fiber core. In one embodiment, the factor ka is increased until the power efficiency stabilizes. In addition to a bare fiber core embodiment, a two-stage fluorescent fiber is provided wherein an active cladding surrounds a portion of the active fiber core having an improved ka factor. The power efficiency of the embodiment is further improved by increasing a difference between the respective indices of refraction of the active cladding and the active fiber core.

NOVEL N X N INTEGRATED CHANNEL WAVEGUIDE OPTICAL CROSSBARS FOR LARGE SCALE HIGH SPEED NON-BLOCKING DATA SWITCHING Final Report, 30 Sep. 1992 - 30 Mar. 1993

Michael Wang 31 May 1993 60 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F49620-92-C-0076)

(AD-A272065; AFOSR-93-0413TR) Avail: CASI HC A04

Physical Optics Corporation proposed a new structure for an optical crossbar based on a multi-wavelength ring resonator tuning/switching. To demonstrate its feasibility, in Phase I, we designed, analyzed, and demonstrated a basic ring resonator tuning/switching element for the crossbar. Two approaches for ring resonator tuning were identified: fiber-based ring resonator and waveguide-based ring resonator. For simplicity of the Phase I concept demonstration, we demonstrated a fiber ring resonator. At HeNe laser wavelengths of 632.8 and 611.9 nm, the fiber resonator demonstrated the desired wavelength selective switching operation. The finesse of the present unoptimized device was measured at about 19 under zero tap coupling, with a potential of exceeding 100. The device provided over 36% throughput with a potential for throughput efficiency of over 80%. The crosstalk was measured at -8 dB with a potential of better than -33 dB. Optimization is possible by reducing the coupler loss. Waveguide fabrication and fiber/waveguide pigtailing experiments were also conducted in Phase I to demonstrate pigtailing capability for crossbar applications. DTIC

X RAY REFLECTION MASKS: MANUFACTURING, CHARACTERIZATION AND FIRST TESTS Thesis [ROETGENREFLEXIONSMASKEN: HERSTELLUNG, CHARAKTERISIERUNG UND ERSTE TESTS]

Stephen Rahn Sep. 1992 63 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Bonn-IR-92-31; ETN-93-93809) Avail: CASI HC A04

SXPL (Soft X-ray Projection Lithography) multilayer mirrors are characterized, laterally structured and then used as reflection masks in a projecting lithography procedure. Mo/Si-multilayer mirrors with a 2d in the region of 14 nm were characterized by Cu-k(alpha) grazing incidence as well as soft X-ray normal incidence reflectivity measurements. The multilayer mirrors were patterned by reactive ion etching with CF4 using a photoresist as etch mask, thus producing X-ray reflection masks. The masks were

tested at the synchrotron radiation laboratory of the electron accelerator ELSA. A double crystal X-ray monochromator was modified so as to allow about 0.5 sq cm of the reflection mask to be illuminated by white synchrotron radiation. The reflected patterns were projected (with an energy of 100 eV) onto a resist and structure sizes down to 8 micrometers were nicely reproduced. Smaller structures were distorted by Fresnel-diffraction. The theoretically calculated diffraction images agree very well with the observed images. ESA

EXAMINATION FOR OPTIMIZATION OF SYNCHROTRON RADIATION SPECTRUM FOR THE X RAY DEPTH LITHOGRAPHY Thesis [UNTERSUCHUNGEN ZUR OPTIMIERUNG DES SPEKTRUMS DER SYNCHROTRONSTRAHLUNG FUER DIE ROENTGENTIEFENLITHOGRAPHIE]
Raimund Dany Jun. 1992 72 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(BONN-IR-92-32; ETN-93-93810) Avail: CASI HC A04

The effect of reducing the vertical distribution of synchrotron radiation on its spectral distribution is examined through resin irradiation. The resulting filter effect is compared to that of absorption filters. Transmission coefficients of titanium, gold, and polyamide were calculated from linear absorption coefficients with the Beer law. The use of a diaphragm in X-ray depth lithography, which is the first step of the LIGA (Lithography Galvanoforming Molding) process, is discussed. A calorimetric device for determining the synchrotron radiation power and distribution was developed and tested. Measurements at the ELSA storage ring show a strong dependence of the vertical emittance on the electron current. ESA

AN OPTICALLY-ASSISTED 3-D CELLULAR ARRAY MACHINE Final Report, 1 Apr. - 30 Sep. 1993
Freddie Lin 5 Nov. 1993 40 p
(Contract N00014-93-C-0021)
(AD-A272683) Avail: CASI HC A03/MF A01

In order to increase the real-time performance of next-generation image processing systems, Physical Optics Corporation (POC) explored a new architectural structure -- a hybrid optically-assisted 3-D cellular array machine. Three techniques are used in this architecture. An analog processing technique is used for front-end high-speed image preprocessing. A digital processing technique is employed for high-precision and highly programmable image processing. An optical interconnect technique is used for high-efficiency high-bandwidth data communication between the analog and digital processing layers. The combination of these three techniques yields a real-time image processing system in a compact 3-D system package with scalable expansion capability. DTIC

OBTAINING SURFACE OPTICAL PROPERTIES FROM SPACE-BASED LIDAR SYSTEMS Technical Report
John R. Hummel, James R. Jones, David R. Longtin, and Richard R. Zeoli 30 Mar. 1993 41 p
(Contract F19628-91-C-0093)
(AD-A272831; LTR93-004; PL-TR-93-2081; SR-5) Avail: CASI HC A03/MF A01

Space-based lidar systems are planned for a number of applications. One application being considered is to use a space-based lidar to infer information about the visibility near the surface from remote or inaccessible areas. This can be accomplished if one can obtain information about the optical properties near the surface. The concept would involve using a lidar on a space platform probing the atmosphere and underlying surface along its orbital path. The purpose of this research has two goals. The first is to determine if a unique relationship can be found at a suitable laser wavelength to relate the extinction coefficients near the surface to the visibility at the surface. The second goal is to determine if lidar backscatter measurements can be inverted in a reasonable fashion to obtain the extinction coefficient near the surface. If these goals can be met, then visibility can be obtained on a routine basis from space-based lidars. This paper presents the results from the study. In the study, a number of different lidar wavelengths have be studied to see if one is more suitable than the others. Also, an examination of the assumptions required to perform the inversion of the lidar equation has been made. DTIC

OPTICAL PROPERTIES OF CHROMIUM AND NEODYMIUM IN ZIRCONIUM - BARIUM - LANTHANUM - ALUMINUM FLUORIDE GLASS Final Report, Oct. 1987 - Sep. 1988
F. E. Hanson and H. H. Caspers Aug. 1993 29 p
(AD-A271609; NCCOSC/RDT/E-TR-1623) Avail: CASI HC A03/MF A01

The optical properties are reported of chromium and neodymium doped in zirconium - barium - lanthanum - aluminum fluoride glass (ZBLA). The fluorescence of Cr(3+) and of co-doped Cr(3+), Nd(3+) glasses is investigated. Fluorescence decay rates of Cr(3+) and Nd(3+) are measured at various temperatures, and the excitation transfer efficiency between Cr(3+) and Nd(3+) is determined. The absorption spectrum of Nd(3+):ZBLA is characterized in terms of the Judd-Ofelt model of crystal field-induced electric-dipole transitions. The three phenomenological intensity parameters for Nd(3+) in ZBLA glass Omega(sub 2,4,6) are compared to those obtained for Nd(3+) in Y3Al5O12, Gd3S2Al3O12, and LHG-8 glass. DTIC

(AD-A273031) Avail: CASI HC A03/MF A01

This quarter focus was on completing a paper containing the details of our calculations on the defect concentration in x = 0.2 Hg(1-x)Cd(x)Te. This involved the refinement of the calculations of all the defects. Our ideas about the formation and annihilation of tellurium precipitates in HgCdTe continue to be developed. Our work on dislocations and the reanalysis of the electronic band structure of narrow-gap HgCdTe was presented at the IRIS materials meeting in August and at the MCT Workshop in October. A paper on the electronic mobility in Hg(0.78)Cd(0.22)Te was submitted for publication in the Journal of Applied Physics. The calculations of the lithium vacancy and niobium antisite formation energies in LiNbO3 were completed and these energies are being incorporated into a thermodynamical analysis. Our calculations on the defect concentrations in ZnSe continue to be refined and preliminary predictions of the dominant defects in that system were made. DTIC

VALIDATION OF THE DESIGN OF A HIGH RESOLUTION ALL-REFLECTION MICHELSON INTERFEROMETER FOR ATMOSPHERIC SPECTROSCOPY M.S. Thesis
Scott M. Carlson Jun. 1993 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272505) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The design of a high resolution plane grating all-reflection Michelson interferometer for ionospheric spectroscopy was analyzed using ray tracing

techniques. This interferometer produces an interference pattern whose spatial frequency is wavelength dependent. The instrument is intended for remote observations of the atomic oxygen triplet emission line profile at 1304 A in the thermosphere from sounding rocket or satellite platforms. The device was modeled using the PC-based ray tracing application, DART, and results analyzed through fourier techniques using the PC with Windows version of the Interactive Data Language (IDL). Through these methods, instrument resolution, resolving power, and bandpass were determined. An analysis of the effects of aperture size and shape on instrument performance was also conducted. DTIC

PHOTONICS AND NONLINEAR OPTICS WITH MOLECULAR MATERIALS AND POLYMERS Final Report, 1 Mar. 1990 - 28 Feb. 1993
Paras N. Prasad 28 Feb. 1993 35 p
(Contract F49620-90-C-0021)
(AD-A271747; AFOSR-93-0806TR) Avail: CASI HC A03/MF A01

We used a multidisciplinary approach to understand the structure-property relationship with an aim towards developing novel second-order and third-order nonlinear materials with enhanced performance for photonics applications. We used a combination of theoretical modeling and experimental measurement of nonlinearities in a group of systematically derivatized structures to understand the structure-property relationship. This approach was extremely useful in designing new structures with enhanced nonlinearities. We have incorporated organic second-order chromophores in sol-gel processed SiO2 and TiO2 composites which have been successfully electrically poled to form stable aligned structures. In-situ poling studies, while monitoring second harmonic generation and electro-optic modulation, were used to study the poling dynamics. The microstructures of sol-gel processed composites were investigated. A combination of optical Kerr-gate, transient absorption, and degenerate four-wave mixing was used along with appropriate theoretical development to understand the nature of resonant third-order optical nonlinearity. Recent advances in photoconductive and bolometric semiconductor detectors for wavelength 1 mm greater than lambda greater than 50 microns are reviewed. Progress in detector performance in this photon energy range has been stimulated by new and stringent requirements for ground based, high altitude, and space-borne telescopes for astronomical and astrophysical observations. The paper consists of chapters dealing with the various types of detectors: Be and Ga doped Ge photoconductors, stressed Ge:Ga devices, and neutron transmutation doped Ge thermistors. Advances in the understanding of basic detector physics and the introduction of modern semiconductor device technology have led to predictable and reliable fabrication techniques. Integration of detectors into functional arrays has become feasible and is vigorously pursued by groups worldwide. DOE

Two types of integrated optical coupling elements were fabricated for fiberoptic sensor applications. This used a process which showed the feasibility of fabricating both optical and electronic functions on the same chip. A bidirectional method of measuring propagation losses from scattered light in a channel waveguide is presented. A new type of polarization splitter based on a Fresnel mirror is demonstrated using silicon nitride as a waveguide core. These circuits are designed to operate at a wavelength of 633 nm. Numerical scalar methods were applied to estimate the behavior of the polarization splitter, and 2, 4, and 16 channel wavelength division multiplexers based on the Fresnel mirror. The theoretical considerations are shown to be in good agreement with experimental data. The silica on silicon technology is studied for telecommunication applications and used for a new wide passband wavelength division multiplexer. For individual titles, see N94-21595 through N94-21603.

A semiconductor process for Si-optoelectronic integrated circuits (OEIC) applications is described. A significant simplicity and compatibility of waveguides and detectors with both types of complementary metal oxide semiconductors (CMOS) processes were achieved by careful consideration of different process steps and device geometry without having to degenerate the performance characteristics of single devices. Two types of passive integrated optical coupling elements with same functions are proposed and demonstrated on silicon substrate. The elements can be hybridized along with semiconductor laser and coupled to a single intensity modulated optical fiber sensor. The reflective concept of a fiber sensor system is adopted in the designs. The comparison of switching properties of the two devices is made. Preliminary results show that an efficiency (100% back reflected to total signal ratio) of -3.2 dB can be obtained and that back reflected signal intensities lower than 0.34% (-24.7 dB) could be observed in on/off conditions. Copyright Avail: CASI HC A02/MF A02

A new on-wafer bidirectional nondestructive measurement method is demonstrated for measuring losses in three dimensional integrated optical

waveguides. A thermally oxidized silicon wafer is used as substrate for silicon nitride multimode waveguides. The measurement is based on p-i-n photodetectors integrated near the waveguide. In order to eliminate the effect of different sensitivities of adjacent p-i-n detectors, the light is launched separately to both ends of the waveguide. The method can be applied to test structures in optoelectronic integrated circuits. ESA

A new type of integrated optic polarization splitter operating at the wavelength of 0.63 micrometers was proposed and demonstrated. The splitting device was fabricated by integrating a single mode silicon nitride input waveguide with a curved total reflecting grating consisting of small parts of ellipses. A preliminary measurement showed 11 dB extinction ratio for TE/TM-separation and 9 dB for TM/TE-separation. ESA

The effect of annealing on the refractive index and the optical uniformity of undoped and phosphorus doped SiO2 films on silicon and quartz substrates is studied. The films are grown using low pressure chemical vapor deposition. Vertical homogeneity of the refractive index is shown to be a relevant measure upon optimizing the annealing treatment for the film. High temperature annealing results in a decrease of the refractive index and an increase in the inhomogeneity of the refractive index in the vertical direction. This is due to the outdiffusion of phosphorus as well as the reduction of compressive stresses in the films. Stresses were considered to be the main reason for the refractive index difference of the order of 0.001 between films grown on silicon and on quartz substrates. ESA

HIGH RESOLUTION, THREE DIMENSIONAL SOFT X RAY IMAGING

J. Trebes, J. Brase, R. Levesque, H. Szoke, T. Yorkey, E. Anderson (California Univ., Berkeley. Lawrence Berkeley Lab.), and C. Jacobsen (State Univ. of New York, Stony Brook.) 12 May 1993 5 p Presented

at the Workshop on Scientific Application of Short Wavelength Coherent Light Source, Stanford, CA, 21 Oct. 1992
(Contract W-7405-eng-48)
(DE93-018867; UCRL-JC-113429; CONF-9210278-2) Avail: CASI HC A01/MF A01

A long term goal of soft x ray imaging has been to make ultrahigh resolution images of unstained, unprepared, wet, live biological microstructures in physiological normal environments. This is now being accomplished with features as small as 300 Angstrom being observed in two dimensional x ray images. While this achievement is remarkable, most complex biological structures are three dimensional in nature and will require three dimensional images on the few hundred Angstrom scale for the structure-function studies required by modern biology. It was endeavored to achieve this three dimensional capability with soft x ray techniques. DOE

MATERIAL OPTIMIZATION FOR HARD X RAY FRESNEL ZONE PLATES
J. Chrzas, W. Yun, B. Lai, D. Legnini, and Y. Xiao 1993 11 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-019569; ANL/XFD/CP-80547; CONF-930722-26) Avail: CASI HC A03/MF A01

Fresnel zone plates have recently been used as the focusing optic for hard x-ray (5 - 11 keV) microscopy techniques. Fresnel zone plates used in the hard x-ray regime focus by constructive interference effects based on the phase modulation of the incident x-ray beam and have experimentally been shown to focus 20 - 30% of the incident photons to less than a one-micron focal spot. The materials of choice for these zone plates have been Al, Cu, Ni, and Au. The focus of this work is the theoretical optimization of the focusing efficiency of phase-modulating Fresnel zone plates in the hard x-ray regime by appropriate material selection. The optimal materials for three different energy ranges will be examined (1 - 5 keV, 5 - 20 keV, and greater than 20 keV), and a discussion of the selection criteria involved will be presented. The current zone plate fabrication techniques will be discussed as they pertain to the physical aspects of the zone plates such as thickness, finest zone width, and aspect ratio. DOE

X RAY CHARACTERIZATION OF A THREE-ELEMENT CONDENSER SYSTEM FOR SOFT X RAY PROJECTION LITHOGRAPHY
D. P. Gaines (Brigham Young Univ., Provo, UT.), G. E. Sommargren, S. P. Vernon, and R. E. English 16 Jun. 1993 7 p Presented at the OSA Topical Meeting on Soft X Ray Projection Lithography, Monterey, CA, 10-12 May 1993
(Contract W-7405-eng-48)
(DE93-019916; UCRL-JC-114074; CONF-9305159-9) Avail: CASI HC A02/MF A01

A three-element condenser system has been fabricated and coated with multilayer reflectors designed to operate at a wavelength of 13.3 nm. The performance of the condenser system was evaluated by measuring the reflectance of the individual condenser mirrors at normal incidence and modeling the system transport efficiency. Although a transport efficiency of 17% should be attainable with this design, actual condenser performance will be reduced because of d-spacing variations on mirror C2 and surface roughness on mirror C3. Replacement mirrors C2 and C3 are being fabricated to recover system performance. DOE

DYNAMICS OF SURFACE THERMAL EXPANSION AND DIFFUSIVITY USING TWO-COLOR REFLECTION TRANSIENT GRATINGS
D. M. Pennington and C. B. Harris (California Univ., Berkeley. Lawrence Berkeley Lab.) Feb. 1993 14 p Presented at the OE/LASE 1993 International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 13-23 Jan. 1993
(Contracts W-7405-eng-48; DE-AC03-76SF-00098)
(DE93-040547; UCRL-JC-111288; CONF-930159-57) Avail: CASI HC A03/MF A01

We report ultrafast measurements of the dynamic thermal expansion of a surface and the temperature dependent surface thermal diffusivity using a two-color reflection transient grating technique. Studies were performed on p-type, n-type, and undoped GaAs(100) samples at several temperatures. Using a 75 fs ultraviolet probe with visible excitation beams, the electronic effects that dominate single color experiments become negligible; thus, surface expansion due to heating and the subsequent contraction caused by cooling provide the dominant influence on the diffracted probe. The diffracted signal was composed of two components, thermal expansion of the surface and heat flow away from the surface, allowing the determination of the rate of expansion as well as the surface thermal diffusivity. At room temperature a signal rise due to thermal expansion was observed, corresponding to a maximum average displacement of approximately 1 A at 32 ps. Large fringe spacings were used; thus, the dominant contributions to the signal were expansion and diffusion perpendicular to the surface. Values for the surface thermal diffusivity of GaAs were measured and found to be in reasonable agreement with bulk values above 50 K. Below 50 K, the diffusivity at the surface was more than an order of magnitude slower than in the bulk due to increased phonon boundary scattering. Comparison of the results with a straightforward thermal model yields good agreement over a range of temperatures (12-300 K). The applicability and advantages of the transient grating technique for studying photothermal and photoacoustic phenomena are discussed. DOE

HOLOGRAPHIC OPTICAL ELEMENTS CORRECTING THE OFF-AXIS ABERRATIONS OF A PARABOLIC MIRROR M.S. Thesis [ELEMENT OPTIQUES HOLOGRAPHIQUES CORRIGEANT LES ABERRATIONS HORS AXE D'UN MIROIR PARABOLIQUE]
Guylain Lemelin Jul. 1990 142 p In FRENCH
(ISBN-0-315-57581-6; CTN-94-60880) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The technology of rotating liquid mirrors provides the potential for constructing reflecting telescopes of high optical quality at larger mirror diameters than those currently achievable using solid glass. However, such mirrors can only operate in a fixed position, and if they are used to observe objects off their optical axis, aberration of the image becomes more significant as the distance off the optical axis increases. Without the use of an optical correction device, the image can be degraded to the point where it is useless. It is proposed that a corrector as simple as a holographic optical element can carry out the necessary correction at a fixed angle of incidence. The theory of scalar diffraction of a monochromatic plane wave by a parabolic mirror is presented along with modeling of aberration phenomena at the mirror surface and at the telescope focus. The computer-aided generation of various types of numerical holographic correctors is presented and two are analyzed. Certain characteristics are put forward in evidence which allow expanding of the useful field of view. Computer program listings are included. CISTI

Fiber optic sensors are starting to be used in specialty application areas where electrical sensors are usually found, such as in aircraft and spacecraft. Fiber optic sensor technology has advantages over its electronic counterparts including small size and weight, immunity to electromagnetic

interference, and ruggedness. The use of fiber interferometers as sensors is reviewed along with methods for demodulating their signals. The principles of path-matched differential interferometry and coherence multiplexing are demonstrated and applied to the design and construction of a system that simultaneously demodulates three fiber Fabry-Perot (FFP) interferometers. The FFP's formed the arms of a delta rosette which were bonded to the surface of an aluminum cantilevered beam and were illuminated with one broadband light source. The receiving interferometer consisted of a bulk Michelson interferometer with three distinct optical paths. A charge coupled device array was used as the detector allowing fringe shifts to be counted on a television monitor. Tensor measurements were made and found to be in good agreement when compared to those obtained from electrical strain gages. Author (CISTI)

PHASE DEMODULATION OF INTERFEROMETRIC FIBER-OPTIC SENSORS M.S. Thesis
Thomas Gordon Beck Mason 1992 113 p
(ISBN-0-315-83425-0; CTN-94-60955) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A variety of interferometric fiber optic sensors is described and compared with a thorough development of their intensity transfer functions and phase strain models. Several different phase demodulation techniques are discussed, and the advantages of the pseudo heterodyne technique are explained. A review of the various types of tunable sources that can be used for pseudo heterodyne phase demodulation is conducted and several practical models are identified. The development of a complete sensor system is reported, and several iterations resulted in improved performance. Techniques for making temperature compensated strain measurements with the strain sensor system are examined, and a preferred technique is demonstrated. The development of a smart structure testbed with a two channel fiber Fabry-Perot sensing system designed to simulate a large space truss is documented. Results of tests with this structure are analyzed, and the sensor system performance is evaluated. Finally, an analysis of future sensing systems for absolute and acoustic sensing is performed on a practical and theoretical basis. Author (CISTI)

PARAMETRIC VARIATIONS OF ION TRANSPORT IN TFTR
S. D. Scott, C. W. Barnes, and D. Ernst (Massachusetts Inst. of Tech., Cambridge.) 18 Mar. 1993 33 p Presented at the US/Japan Workshop on Ion Temperature Gradient Driven Turbulent Transport, Austin, TX, 11-14 Jan. 1993
(Contract W-7405-eng-36)
(DE93-012653; LA-UR-93-1255; CONF-9301107-1) Avail: CASI HC A03/MF A01

This paper is divided into three roughly independent sections. The first is a historical review of the twenty year history of experimental ion heat transport measurements from many tokamaks. The second is a study of ion heat transport in Ohmic TFTR plasmas which shows that chi(sub i) is similar to chi(sub e) approximately equal to chi(sub i)(sup neo). Thus, ion heat transport is demonstrated to be strongly anomalous even the absence

of auxiliary heating. The third section describes the variation of chi(sub i) with local ion temperature in TFTR during auxiliary heating, with emphasis on characterizing the differences between transport in the L-mode and supershot regimes. The results are consistent with the conjecture that improved ion energy confinement in supershot plasmas is caused by a high ratio of T(sub 1)/T(sub e). DOE

LONGITUDINAL BEAM DYNAMICS FOR HEAVY ION FUSION USING WARPrz
Debra A. Callahan, A. Bruce Langdon, Alex Friedman, and Irving Haber (Naval Research Lab., Washington, DC.) 22 Feb. 1993 10 p Presented at the 1993 Computational Accelerator Physics Conference, Pleasanton, CA, 22-26 Feb. 1993
(Contracts W-7405-eng-48; DE-AI05-92ER-54177; DE-AI05-83ER-40112)
(DE93-019154; UCRL-JC-112247; CONF-930269-20) Avail: CASI HC A02/MF A01

WARPrz is a 2.5 dimensional, cylindrically symmetric, electrostatic, particle-in-cell code. It is part of the WARP family of codes which has been developed to study heavy ion fusion driver issues. WARPrz is being used to study the longitudinal dynamics of heavy ion beams including a longitudinal instability that is driven by the impedance of the LINAC accelerating modules. This instability is of concern because it can enhance longitudinal momentum spread; chromatic abhoration in the lens system restricts the amount of momentum spread allowed in the beam in the final focusing system. The impedance of the modules is modeled by a continuum of resistors and capacitors in parallel in WARPrz. We discuss simulations of this instability including the effect of finite temperature and reflection of perturbations off the beam ends. We also discuss intermittency of axial confining fields ('ears' fields) as a seed for this instability. DOE

THE BEST OF GYMNOS: A USERS GUIDE
D. W. Hewett and D. J. Larson Aug. 1993 104 p
(Contract W-7405-eng-48)
(DE93-041275; UCRL-ID-110499) Avail: CASI HC A06/MF A02

The code GYMNOS is a 2.5D magnetostatic PIC code that is distinguished from the multitude of similar codes by its ability to handle boundary conditions and internal structures. This code was started during the period from December 1987 and the major sections were completed and in routine use by the end of 1990. The code is written in R-Z geometry (axisymmetric m=0 only) but could easily be modified to handle an X-Z configuration. The several competitors of this code, having similar (but we believe less general) capabilities, distinguish themselves in a different way: they have very formal, thick instruction manuals and usually command an army of people to maintain both the code and said manual. We are attempting to convince the reader that GYMNOS is better in these two regards. Offered is a description of a code with a great deal of physics capability coupled with no interactive graphics capability and very little system capability. These later two subjects contribute most of the complexity in both the code and manual in the competition! Expressed another way, the user will almost never be thwarted by unexpected system changes on Friday afternoon. The price extracted is that the user is required to monitor/babysit runs so that output is 'hand-delivered' to the output medium and properly archived to prevent loss. A further spinoff of this simplicity is that 'single pilot' operation is easy. And, the only manual is this modest document. DOE

TRANSIENT THERMAL ANALYSIS OF CRYOCONDENSATION PUMP FOR JET
C. B. Baxi and W. Obert (Joint European Torus Project, Abingdon, England.) Aug. 1993 8 p Presented at the International Cryogenic Engineering Conference and International Cryogenic Materials Conference, Albuquerque, NM, 12-16 Jul. 1993
(Contract DE-AC03-89ER-51114)
(DE93-040372; GA-A-20941; CONF-930703-33) Avail: CASI HC A02/MF A01

A cryopump with pumping speed of 50,000 1/sec is to be installed in the Joint European Torus (JET) as part of the pumped divertor. The purpose of this pump is to control the plasma impurities. The pump consists of a helium panel cooled by supercritical helium and a nitrogen shield cooled by liquid nitrogen. This paper presents the following transient thermal flow analysis for this cryopump: (1) consequences of loss of torus vacuum on helium panel; and (2) cool down of the nitrogen shield form 300 K to 80 K. SPACE-CHARGE DOMINATED BEAM TRANSPORT IN MAGNETIC QUADRUPOLES WITH LARGE APERTURE RATIOS
W. F. Fawley Aug. 1993 20 p
(Contract DE-AC03-76SF-00098)
(DE93-040443; LBL-33608; HIFAN-614) Avail: CASI HC A03/MF A01

This memo summarizes the results of calculations of the usable aperture ratio for short period, magnetic quadrupoles for both ILSE magnet designs and the more general, heavy-ion fusion (HIF) 'driver' case. From both analytic decomposition of the magnetic field in a periodic lattice and particle code simulations of beam transport, we find that fringe field nonlinearities and associated emittance growth become quite large when the beam radius a(sub b) exceeds one-quarter or so of the half-lattice period L. For ILSE, there are a number of magnet designs which can transport the specified line charge without any significant difficulties, primarily because the ratio a(sub b)/L is of order 0.1 or less. For larger sized beams such as one might employ in the low energy part of a driver, there are problems with properly matching the beam to the transport lattice in both the macroscopic and microscopic sense as a(sub b)/L exceeds 0.2. For even larger aperture ratios, particle loss can occur, with the threshold in beam radius roughly scaling inversely with (sigma)(sub o), the single particle phase advance per lattice period. DOE

FAST ION BEHAVIOR DURING NEUTRAL BEAM INJECTION IN ATF
M. R. Wade, C. E. Thomas, R. J. Colchin, J. A. Rome, A. C. England, R. H. Fowler, and S. C. Aceto (Rensselaer Polytechnic Inst., Troy, NY.) 1993 8 p Presented at the 9th International Atomic Energy Agency Workshop on Stellarators, Garching, Germany, 10-14 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-040267; CONF-9305210-3) Avail: CASI HC A02/MF A01

In stellarators, single-particle confinement properties can be more complex than in their tokamak counterparts. Fast-ion behavior in tokamaks has been well characterized through an abundance of measurements on various devices and in general has been shown to be consistent with classical slowing-down theory, although anomalous ion behavior has been observed during intense beam injection in ISX-B, during fishbone instabilities in PDX, and in experiments on TFR. In contrast, fast ion behavior in stellarators is not as well established experimentally with the primary experiments to date focusing on near-perpendicular or perpendicular neutral beam injection (NBI) on the Wendelstein 7-A stellarator and Heliotron-E. This paper addresses fast-ion confinement properties in a large aspect ratio, moderate shear stellarator, the Advanced Toroidal Facility, during tangential NBI. The primary data used in this study are the experimentally measured energy spectra of charge-exchange neutrals escaping from the plasma, using a two-dimensional scanning neutral particle analyzer. This diagnostic method is well established, having been used on several devices since the early 1970's. Various aspects of fast-ion behavior are investigated by comparing these data with computed theoretical spectra based on energetic ion distributions derived from the fast ion Fokker-Planck equation. Ion orbits are studied by computer orbit following, by the computation of J(sup *) surfaces, and by Monte Carlo calculations. DOE

RADIATION OF PLASMA WAVE WINGS THROUGH AN ELECTRODYNAMIC TETHER SATELLITE SYSTEM WITH ANY SHARP ANGLE GEOMETRY [ABSTRAHLUNG VON PLASMAWELLENFLUEGELN DURCH EIN ELEKTRODYNAMISCHES FESSELSATELLITENSYSTEM BEI BELIEBIGER SCHIEFWINKLIGER GEOMETRIE]

Andrea Luettgen 1992 110 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Rept-85; ETN-93-95067) Avail: CASI HC A06

A model for the far field interaction between an electrodynamic tether satellite system and its ionospheric plasma environment is developed. The angles between cable orientation, plasma flow direction, and magnetic field were supposed to be different from 90 degrees. The charge exchange was assumed to regularly occur on a finite distance along the streamflow. Magnetic field was homogeneous and time constant; cold plasma approximation was used for the ionospheric plasma which only contained electrons and one ion species. Field parallel current density in Alfven wings, electric field in plasma and related impedence were calculated and their variations with magnetic field orientation were discussed. It is shown that frequency area, for which pure, nonevanescent wave propagation occurs, strongly varies with magnetic field orientation. It is found that current density in magnetic field direction has a stronger resolution of ideal Alfven wing structure by lower perturbation lengths and so by higher characteristic excitation frequency. Wave impedance was calculated with fixed magnetic field vector angle as a function of perturbation length; it can be concluded that oscillation area of impedance values drops with increasing perturbation lengths. HEAVY ION FUSION INJECTOR EXPERIMENTS

S. Eylon, E. Henestroza, H. Rutkowski, S. Yu, D. Grote, Y. J. Chen, and D. Hewett May 1993 15 p Presented at the International Symposium on Heavy Ion Fusion, Frascati, Italy, 25-28 May 1993
(Contract DE-AC03-76SF-00098)
(DE93-019188; LBL-33801; CONF-9305136-14) Avail: CASI HC A03/MF A01

We report on three experiments performed in connection with the 2 MV electrostatic quadrupole (ESQ) injector under construction at Lawrence Berkeley Laboratory. Scaled experiments have been conducted to study possible beam emittance growth due to beam aberrations in an ESQ injector. The experiment uses the SBTE (Single Beam Transport Experiment) accelerator system, quarter-scale ESQ setup and a potassium ion diode source. Measured emittance growth changes significantly with variations in current and diode energy, in good agreement with theoretical predictions. In addition, beam transport experiments were performed in a 1 MV axisymmetric electrostatic aperture column using a zeolite 1 inch diameter potassium ion source. Experimental measurements in good agreement with 2-1/2 D simulations showed that low emittance beams can be produced in axisymmetric structures. Finally, ESQ breakdown voltage tests without beam were performed at up to two times the quadrupole working voltage. DOE

OPTICAL DIAGNOSTIC INSTRUMENT FOR MONITORING ETCH UNIFORMITY DURING PLASMA ETCHING OF POLYSILICON IN A CHLORINE-HELIUM PLASMA

W. A. Hareland and R. J. Buss Jun. 1993 15 p
(Contract DE-AC04-76DP-00789)
(DE93-019582; SAND-93-0455) Avail: CASI HC A03/MF A01

Non-uniform etching is a serious problem in plasma processing of semiconductor materials and has important consequences in the quality and yield of microelectronic components. In many plasmas, etching occurs at a faster rate near the periphery of the wafer, resulting in nonuniform removal of specific materials over the wafer surface. This research investigates in situ optical diagnostic techniques for monitoring etch uniformity during plasma processing of microelectronic components. The authors measure 2-D images of atomic chlorine at 726 nm in a chlorine-helium plasma during plasma etching of polysilicon in a parallel-plate plasma etching reactor. The 3-D distribution of atomic chlorine is determined by Abel inversion of the plasma image. The experimental results show that the chlorine atomic emission intensity is at a maximum near the outer radius of the plasma and decreases toward the center. Likewise, the actual etch rate, as determined by profilometry on the processed wafer, is approximately 20% greater near the edge of the wafer than at its center. There is a direct correlation between the atomic chlorine emission intensity and the etch rate of polysilicon over the wafer surface. Based on these analyses, 3-D imaging would be a useful diagnostic technique for in situ monitoring of etch uniformity on wafers. DOE

BETA-LIMITING INSTABILITIES IN D3-D DISCHARGES WITH LARGE BOOTSTRAP CURRENT

E. J. Strait, T. S. Taylor, A. D. Turnbull, M. S. Chu, J. R. Ferron, L. L. Lao, and T. H. Osborne May 1993 4 p Presented at the 20th European Conference on Controlled Fusion and Plasma Physics, Lisbon, Portugal, 26-30 Jul. 1993
(Contract DE-AC03-89ER-51114)
(DE93-015476; GA-A-21301; CONF-930720-10) Avail: CASI HC A01/MF A01

In reactor-relevant discharges with high beta and low collisionality, the beta limit may be reduced by the presence of a large bootstrap current density near the edge of the plasma. The combination of a large current density and a large pressure gradient may destabilize low-n ideal kink modes localized near the plasma edge. This hypothesis is consistent with the behavior of high-performance discharges in DIII-D, in which the ELM-free phase with good energy confinement often ends with a rapidly growing low-n MHD instability. A large bootstrap current density can occur near the edge of H-mode discharges, even at moderate values of volume-averaged beta, owing to the large pressure gradient associated with the H-mode transport barrier. In discharges with finite aspect ratio and low to moderate collisionality, the bootstrap current density is proportional to the pressure gradient rather than the density gradient and thus becomes large near the edge of high beta and H-mode discharges. A large bootstrap current density is found near the edge of low density H-mode and VH-mode discharges in DIII-D, as predicted by transport simulations and confirmed by equilibrium reconstructions. THEORETICAL AND NUMERICAL STUDIES IN MAGNETIC FUSION

1993 11 p
(Contract DE-FG02-86ER-53240)
(DE94-000536; DOE/ER-53240/5) Avail: CASI HC A03/MF A01

This past year has been devoted to the development of analytic and numerical kinetic theory for the edge physics problem in Tokamaks. For the charged particles the general formal problem involves the solution of the system of coupled drift-kinetic equations. Near a diverter, the set of equations must be supplemented by Boltzmann equations for the uncharged species, and the situation is complicated by wall chemistry and sheaths. The full problem is clearly beyond the ability of the current best in available analytic and numerical methods. Thus we have begun by considering simplified model kinetic theory models in order to explore phenomena and develop analytic and numerical techniques. The first effort was to use the kinetic equation of discharge theory, which while not quantitative, provides the easiest problem. Next we have completely solved a kinetic theory

problem using the Lorentz gas approximation for the collision term. This has provided analytic and computational tools for use in dealing with the kinetic equation including energy diffusion. In order to deal most simply with energy diffusion we have developed a simple model of the collision terms C(sub j) which conserves number and for self collisions, also conserves energy and momentum. It lends itself to rapid accurate computation. The associated solutions of the kinetic equation should be semiquantitative and provide a useful tool for the rapid exploration of edge phenomena and the development of first approximations required for the iterative solution of the full kinetic equation. (DE94-000779; DOE/ER-53218/23) Avail: CASI HC A03/MF A01

The research performed under this grant during the past year has been concentrated on the following several key tokamak ICRF (Ion Cyclotron Range of Frequencies) coupling, heating, and current drive issues. We have made progress in developing a '3-D' cavity backed antenna array code to examine ICRF coupling to general plasma edge profiles. The effects of the finite antenna length and feeders as well as Faraday shield blade angle are being examined. We are also developing an analysis to examine large k(perpendicular)(rho) gyroradius interaction between alpha or beam particles and ICRF waves. This topic has important applications in the areas of ICRF heating for deuterium-tritium fusion plasmas, TAE modes, ash removal, and minority ion current drive. Research progress, publications, and conference and workshop presentations are summarized in this report. DOE

THREE-WAVE RESONANT INTERACTION IN A THIN LAYER
Aug. 1993 11 p Sponsored by ONR and AFOSR
(AD-A272331) Avail: CASI HC A03/MF A01

We analyze in detail conversion of a pump wave into two daughter waves (DW's) on an infinitely thin nonlinear layer, assuming that the conversion is initiated by weak seed pulses of the DW's. Three cases corresponding to different signs of the group velocities of the DW's are considered separately. In the case when both velocities are opposite to that of the pump wave, a threshold value of the 'strength' of the nonlinear layer is found, above which oscillations between the conversion and the inverse process of recombination set in. In the case when the DW group velocities have different signs, the shapes of the generated DW pulses do not depend upon shapes of the corresponding 'seed' pulses. In this case, multiple solutions are possible, provided the nonlinearity is strong enough. DTIC

IMPACT OF COPPER VAPOUR CONTAMINATION ON ARGON ARCS
Salim Akbar 1990 24 p Original contains color illustrations
Avail: CASI HC A03/MF A01

A fast, accurate, and comprehensive emission spectroscopic set up has been employed to study the impact of copper vapor on an Ar-Cu mixture plasma. Temperature profiles in the arc have been determined in the absence of Cu vapor and then in its presence, using the absolute line intensity method for an Ar spectral line; these profiles are compared with temperature profiles derived from relative intensities of Cu I lines. Temperature profiles derived from relative intensity of Cu I lines are used to calculate the radial density distribution of copper atoms in the arc. The following observations are made from the resulting atomic number densities: the copper vapor concentrates in the fringes of the arc, with atomic number densities up to 8.6 x 10(exp 11) cm(exp -3); and Cu atomic number densities in the core of the arc are small. Two photon laser induced fluorescence (TALIF) has been developed as a convenient and reliable diagnostic of H atoms in plasma processing environments. It has high spatial and temporal resolution, good sensitivity, and the capability of absolute concentration measurements. Detailed diagnostics have been carried out in plasma reactors with and without semiconducting wafers. These measurements have led to a model that incorporates H atom production, diffusion, and surface recombination. This model has accurately predicted both the spatial and temporal behavior of the H-atom concentration in a plasma processing environment. DTIC

PLASMA-PUFF INITIATION OF HIGH COULOMB TRANSFER SWITCHES
Kwang S. Han, Demetrius D. Venable, Ja H. Lee, Eun H. Choi, Y. K. Kim, J. H. Kim, and D. X. Nguyen *In its* Research on Plasma-Puff Initiation of High Coulomb Transfer Switches 1993 10 p (For primary document see N94-21289 05-75)
Avail: CASI HC A02/MF A01

The plasma-puff triggering mechanism based on a hypocycloidal pinch geometry was investigated to determine the optimal operating conditions for an azimuthally uniform surface flashover which initiates plasma-puff under wide ranges of fill gas pressures of Ar, He and N2. The optimal fill gas pressures for the azimuthally uniform plasma-puff were about 120 mTorr less than P(sub opt) less than 450 Torr for He and N2. For Argon 20 mTorr is less than P(sub opt) is less than 5 Torr. The inverse pinch switch was triggered with the plasma-puff and the switching capability under various electrical parameters and working gas pressures of Ar, He and N2 was determined. It was also shown that the azimuthally uniform switching discharges were dependent on the type of fill gas and its fill pressure. A new concept of plasma-focus driven plasma-puff was also discussed in comparison with hypocycloidal pinch plasma-puff triggering. The main discharge of the inverse pinch switch with the plasma-focus driven plasma-puff trigger is found to be more azimuthally uniform than that with the hypocycloidal pinch plasma-puff trigger in a gas pressure region between 80 mTorr and 1 Torr. In order to assess the effects of plasma current density on material erosion of electrodes, emissions from both an inverse-pinch plasma switch (INPIStron) and from a spark gap

switch under test were studied with an optical multichannel analyzer (OMA). The color temperature of the argon plasma was approximately 4,000 K which corresponded with the peak continuum emission near 750 nm. There are the strong line emissions of argon in the 650 - 800 nm range and a lack of line emissions of copper and other solid material used in the switch. This indicates that the plasma current density during closing is low and the hot spot or hot filament in the switch is negligible. This result also indicates considerable reduction of line emission with the INPIStron switch over that of a spark-gap switch. However, a strong carbon line emission exists due to vaporization of the plastic insulator used. In order to reduce the vaporization of the insulator, the plexiglass insulating material of INPIStron was replaced with Z-9 material. A comparative study of the INPIStron and a spark gap also reveals that the INPIStron, with a low impedance of Z = 9 ohms, can transfer a high voltage pulse with a superior pulse-shape fidelity over that of a spark gap with Z = 100 ohms. COMPARATIVE STUDY OF INPIStron AND SPARK GAP
Kwang S. Han and Ja H. Lee *In its* Research on Plasma-Puff Initiation of High Coulomb Transfer Switches 1993 4 p (For primary document see N94-21289 05-75)
Avail: CASI HC A01/MF A01

An inverse pinch plasma switch, INPIStron, was studied in comparison to a conventional spark gap. The INPIStron is under development for high power switching applications. The INPIStron has an inverse pinch dynamics, opposed to Z-pinch dynamics in the spark gap. The electrical, plasma dynamics and radiative properties of the closing plasmas have been studied. Recently the high-voltage pulse transfer capabilities or both the INPIStron and the spark gap were also compared. The INPIStron with a low impedance Z = 9 ohms transfers 87 percent of an input pulse with a halfwidth of 2 mu s. For the same input pulse the spark gap of Z = 100 ohms transfers 68 percent. Fast framing and streak photography, taken with an TRW image converter camera, was used to observe the discharge uniformity and closing plasma speed in both switches. In order to assess the effects of closing plasmas on erosion of electrode material, emission spectra of two switches were studied with a spectrometer-optical multi channel analyzer (OMA) system. The typical emission spectra of the closing plasmas in the INPIStron and the spark gap showed that there were comparatively weak carbon line emission in 658.7 nm and copper (electrode material) line emissions in the INPIStron, indicating low erosion of materials in the INPIStron. INPIStron SWITCHED PULSED POWER FOR DENSE PLASMA PINCHES Abstract Only
Kwang S. Han and Ja H. Lee *In its* Research on Plasma-Puff Initiation of High Coulomb Transfer Switches 1993 1 p Meeting of the 9th International Pulsed Conference held in Albuquerque, NM, 21-23 Jun. 1993 (For primary document see N94-21289 05-75)
(Contract NAG1-970; N00014-89-J-1653)
Avail: CASI HC A01/MF A01

The inverse plasma switch INPIStron was employed for 10kJ/40kV capacitor bank discharge system to produce focused dense plasmas in hypocycloidal-pinch (HCP) devices. A single unit and an array of multiple HCP's were coupled as the load of the pulsed power circuit. The geometry and switching plasma dynamics were found advantageous and convenient for commutating the large current pulse from the low impedance transmission line to the low impedance plasma load. The pulse power system with a single unit HCP, the system A, was used for production of high temperature plasma focus and its diagnostics. The radially running down plasma dynamics, revealed in image converter photographs, could be simulated by a simple snow-plow model with a correction for plasma resistivity. The system B with an array of 8-HCP units which forms a long coaxial discharge chamber was used for pumping a Ti-sapphire laser. The intense UV emission from the plasma was frequency shifted with dye-solution jacket to match the absorption band of the Ti crystal laser near 500 nm. An untuned laser pulse energy of 0.6 J/pulse was obtained for 6.4 kJ/40 kV discharge, or near 103 times of the explosion limit of conventional flash lamps. For both systems the advantages of the INPIStron were well demonstrated: a single unit is sufficient for a large current (greater than 50 kA) without increasing the system impedance, highly reliable and long life operation and implied scalability for the high power ranges above I(sub peak) = 1 MA and V(sub hold) = 100 kV. SHEAR FLOW GENERATION BY REYNOLDS STRESS AND SUPPRESSION OF RESISTIVE g-MODES
H. Sugama (National Inst. for Fusion Science, Nagoya, Japan.) and W. Horton Aug. 1993 37 p
(Contract DE-FG05-80ET-53088)
(DE93-040911; IFSR-617; DOE/ET-53088/617) Avail: CASI HC A03/MF A01

Suppression of resistive g-mode turbulence by background shear flow generated from a small external flow source and amplified by the fluctuation-induced Reynolds stress is demonstrated and analyzed. The model leads to a paradigm for the low-to-high (L-H) confinement mode transition. To demonstrate the L-H transition model, single-helicity nonlinear fluid simulations using the vorticity equation for the electrostatic potential, the pressure fluctuation equation, and the background poloidal flow equation are used in the sheared slab configuration. The relative efficiency of the external flow and the Reynolds stress for producing shear flow depends on the poloidal flow damping parameter nu which is given by neoclassical theory. For large nu, the external flow is a dominant contribution to the total background poloidal shear flow and its strength predicted by the neoclassical theory is not enough to suppress the turbulence significantly. In contrast, for small nu, we show that the fluctuations drive a Reynolds stress that becomes large and suddenly, at some critical point in time, shear flow much larger than the external flow is generated and leads to an abrupt, order unity reduction of the turbulent transport just like that of the L-H transition in tokamak experiments. It is also found that, even in

the case of no external flow, the shear flow generation due to the Reynolds stress occurs through the nonlinear interaction of the resistive g-modes and reduces the transport. To supplement the numerical solutions we derive the Landau equation for the mode amplitude of the resistive g-mode taking into account the fluctuation-induced shear flow and analyze the opposite action of the Reynolds stress in the resistive g turbulence compared with the classical shear flow Kelvin-Helmholtz (K-H) driven turbulence. ON EFFECTS OF A LOCAL PLASMA DENSITY GROWTH DUE TO PONDEROMOTIVE FORCES AT FAST WAVE LAUNCHING IN TOKAMAKS
V. Petrzilka Dec. 1992 14 p
(IPPCZ-328) Avail: CASI HC A03/MF A01

Nonlinear changes of the reflection coefficient at fast wave launching by a waveguide array are computed also for the case of an eventual fast wave experiment on the FTU tokamak. In case of low plasma density gradients, the reflection coefficient may significantly change for the wave power in the range of several kilowatts per centimeter square due to the ponderomotive force effects. THE ANGULAR VELOCITY SPREAD OF REB INDUCED BY MAGNETIC FIELD DISCONTINUITY
P. Vrba and V. Piffl Mar. 1993 29 p
(IPPCZ-331) Avail: CASI HC A03/MF A01

The generation and propagation of relativistic electron beams (REB) through the thin foil into a plasma column was studied numerically. Two types of electron scattering on the anode foil were compared. The first one is multiple scattering of fast electrons with atomic nuclei. The second one arises when the magnetic field lines are discontinuous on vacuum-plasma boundary. It was pointed out, that these two types of scattering strongly affect the excitation of two stream instability. Author (revised)

RADIAL DIFFUSION OF TOROIDALLY TRAPPED PARTICLES INDUCED BY LOWER HYBRID AND FAST WAVES
L. Krlin Oct. 1992 7 p
(IPPCZ-327) Avail: CASI HC A02/MF A01

The interaction of RF field with toroidally trapped particles (bananas) can cause their intrinsic stochasticity diffusion both in the configuration and velocity space. In RF heating and/or current drive regimes, RF field can interact with plasma particles and with thermonuclear alpha particles. The aim of this contribution is to give some analytical estimates of induced radial diffusion of alphas and of ions. Author (revised)

ON THE STABILITY OF SHEAR-ALFVEN VORTICES
D. Jovanovic and W. Horton Aug. 1993 23 p
(Contract DE-FG05-80ET-53088)
(DE93-040912; DOE/ET-53088/618; IFSR-618) Avail: CASI HC A03/MF A01

Linear stability of shear-Alfven vortices is studied analytically using the Lyapunov method. Instability is demonstrated for vortices belonging to the drift mode, which is a generalization of the standard Hasegawa-Mima vortex to the case of large parallel phase velocities. In the case of the convective-cell mode, short perpendicular-wavelength perturbations are stable for a broad class of vortices. Eventually, instability of convective-cell vortices may occur on the perpendicular scale comparable with the vortex size, but it is followed by a simultaneous excitation of coherent structures with better localization than the original vortex. PARTICLE BEHAVIOR IN AN ECR PLASMA ETCH TOOL
M. G. Blain, G. D. Tipton, W. M. Holber (International Business Machines Corp., Yorktown Heights, NY.), P. L. Westerfield, and K. L. Maxwell (SEMATECH, Austin, TX.) 1993 26 p Presented at the North Atlantic Treaty Organization Advanced Research Workshop, Toulouse, France, 30 Aug. - 3 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-040343; SAND-93-1981C; CONF-9308151-1) Avail: CASI HC A03

Sources of particles in a close-coupled electron cyclotron resonance (ECR) polysilicon plasma etch source include flaking of films deposited on chamber surfaces, and shedding of material from electrostatic wafer chucks. A large, episodic increase in the number of particles added to a wafer in a clean system is observed more frequently for a plasma-on than for a gas-only source condition. For polymer forming process conditions, particles were added to wafers by a polymer film which was observed to fracture and flake away from chamber surfaces. The presence of a plasma, especially when rf bias is applied to the wafer, caused more particles to be ejected from the walls and added to wafers than the gas-only condition; however, no significant influence was observed with different microwave powers. A study of effect of electrode temperatures on particles added showed that thermophoretic forces are not significant for this ECR configuration. Particles originating from the electrostatic chuck were observed to be deposited on wafers in much larger numbers in the presence of the plasma as compared to gas-only conditions. DOE

[ON PLASMA EDGE SPECTROSCOPY AND SPECTROSCOPIC STUDIES OF IMPURITY DENSITIES AND IMPURITY TRANSPORT]
K. Behringer Jun. 1992 32 p Presented at 4th Workshop on Magnetic Confinement Fusion: Diagnostics for Tokamaks and Stellarators, Santander, Spain, 22-24 Jun. 1992
(IPF-92-2; ETN-93-94207) Avail: CASI HC A03/MF A01

Atomic physics models for the interpretation of plasma edge spectroscopy measurements are discussed. Plasma edge spectroscopy is used to investigate atom and ion particle flux densities at the boundary of tokamaks or stellarators. Results are shown for oxygen, carbon and chromium in JET. Molecular particle fluxes, like H2, D2, and CH4 are considered. The interpretation of the shape and intensity of molecular band emission is explained, and results are presented with respect to chemical carbon production. The mechanisms of impurity screening at the plasma edge are investigated and respective mesurements are shown. Spectrometers and spectra, mainly from JET, are discussed with respect to diagnostic potential and calibration problems. Spatial scan facilities of multichord diagnostics are essential for transport investigations, and several possibilities are shown. For individual titles, see N94-21803 through N94-21804.

PLASMA EDGE SPECTROSCOPY
K. Behringer *In its* On Plasma Edge Spectroscopy and Spectroscopic Studies of Impurity Densities and Impurity Transport Jun. 1992 17 p
(For primary document see N94-21802 05-75)
Avail: CASI HC A03/MF A01

Atomic physics models for the interpretation of plasma edge spectroscopic measurements are discussed. Spectroscopy of the plasma edge, mainly in the visible range, provides information on hydrogen and impurity influxes, on impurity production measurements and on particle confinement. Some basic processes determining the population of excited levels are presented leading to the corona excitation balance and to collisional radiative models. These were discussed for the special case of helium. A first application of plasma edge spectroscopy is the investigation of atom and ion particle flux densities at the boundary of tokamaks or stellarators. Results are shown for oxygen, carbon and chromium in JET. Molecular particle fluxes, like H2, D2 and CH4 are then focused upon. The interpretation of the shape and intensity of molecular band emission is explained, and results are presented with respect to chemical carbon production. The mechanisms of impurity screening at the plasma edge are investigated and respective measurements are shown. ESA

SPECTROSCOPIC STUDIES OF IMPURITY DENSITIES AND IMPURITY TRANSPORT
K. Behringer *In its* On Plasma Edge Spectroscopy and Spectroscopic Studies of Impurity Densities and Impurity Transport Jun. 1992 15 p (For primary document see N94-21802 05-75)
Avail: CASI HC A03/MF A01

Spectrometers and spectra, mainly from JET, are discussed with respect to diagnostic potential and calibration problems. Spatial scan facilities or multichord diagnostics are essential for transport investigations, and several possibilities are shown. The interpretation of spectral line radiation usually requires the availability of impurity transport codes, which calculate the ionization balance in the presence of transport, the line emissivities and the total impurity radiation. Some atomic physics prerequisites of such codes are discussed. Theoretical and experimental approaches to the transport problem are investigated using ASDEX and JET results for anomalous transport. The occasional observation of neoclassical accumulation, for example after pellet injection, is presented and respective modeling is described. Some H mode transport phenomena are mentioned. ESA

EDGE PLASMA EXPERIMENTS ON CASTOR TOKAMAK
F. Zacek, J. Stockel, J. Badalec, K. Jakubka, P. Kletecka, L. Kryska, V. Kriha (Technical Univ. of Prague, Czechoslovakia.), V. Svoboda (Technical Univ. of Prague, Czechoslovakia.), J. Petrzilka (Karlova Univ., Prague, Czechoslovakia.), and I. Voitsekhovich (Kurchatov, I. V. Inst. of Atomic Energy, Moscow, USSR.) Apr. 1993 13 p Presented at the KFA-IPP-KFKI-RMKI Joint Workshop on the Use of Atomic Beams in Plasma Experiments, Budapest, 29 Mar. - 2 Apr. 1993
(IPPCZ-332) Avail: CASI HC A03/MF A01

The important role of the edge plasma in the global particle and energy balance in tokamaks is well recognized. However, the complexity of all processes involved in the particle and energy losses hinders to create an appropriate theoretical model of anomalous transport in tokamaks up to now. It seems to be evident only that the anomalous transport relies in the turbulent character of tokamak periphery. However, complete and exhaustive experimental data from the tokamaks periphery are still necessary. The main aim of the experimental research on tokamak CASTOR is focused to investigations of the edge plasma characteristics in the regimes with the improved confinement. Such regimes are reached in CASTOR with lower hybrid current drive or by plasma edge polarization. Results of these investigations indicate that the link between the global confinement and the level of edge fluctuations is more complex than it is generally assumed. The contribution brings a short survey of experimental activities undertaken on the tokamak CASTOR in this direction. Author (revised)

SPECTRAL CHARACTERIZATION OF LITHOGRAPHIC SOURCES
C. Cerjan Jun. 1993 20 p Presented at the Optical Society of America Topical Meeting on Soft X Ray Projection Lithography, Monterey, CA, 10-12 May 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-019941; UCRL-JC-114072; CONF-9305159-8) Avail: CASI HC A03

Spectral data collected in recent laser-plasma experiments at LLNL for Sn are compared to simulation results in order to more fully characterize the plasma properties, especially electron temperature and density. These plasma conditions determine the ionization states achieved by the material and the consequent radiative emission. Synthetic spectra are produced using very detailed radiating line positions and oscillator strengths calculated from extensive multi-configuration Dirac-Fock computations. Better quantitative agreement with experimental conversion efficiencies in the laser intensity regime of interest to projection soft x-ray lithography is obtained using this atomic database. The spectral characterization thus validates the general reliability of the simulations. DOE

A MOVING FINITE ELEMENT MODEL OF THE TOKAMAK SCRAPEOFF LAYER
A. H. Glasser and A. P. Kuprat 1993 10 p Presented at the 4th International Workshop on Plasma Edge Theory in Fusion Devices, Varenna, Italy, 4-6 Oct. 1993
(Contract W-7405-eng-36)
(DE94-000673; LA-UR-93-3502; CONF-931070-1) Avail: CASI HC A02/MF A01

Most numerical simulations of the tokamak scrapeoff layer use a mapping to flux coordinates and a piecewise equidistributed grid in those coordinates to resolve the multiple length scales and anisotropy characteristic of this problem. We have developed an alternative numerical method using simple cylindrical coordinates with a complex adaptive grid scheme. It is based on an understructured grid of traingles which move adaptively, aligning themselves with the magnetic field and concentrating in regions of sharp gradients. DOE

A UNIFIED MONTE CARLO INTERPRETATION OF PARTICLE SIMULATIONS AND APPLICATIONS TO NONNEUTRAL PLASMAS
A. Y. Aydemir Sep. 1993 30 p
(Contract DE-FG05-80ET-53088)
(DE94-001231; DOE/ET-53088/602; IFSR-602) Avail: CASI HC A03/MF A01

Using a 'Monte Carlo interpretation' of particle simulations, a general description of low-noise techniques is developed in terms of well-known Monte Carlo variance reduction methods. These techniques are applied to linear and nonlinear studies of pure electron plasmas in cylindrical geometries, with emphasis on the generation and nonlinear evolution of electron vortices. Long-lived $l = 1$ and $l = 2$ vortices, and others produced by unstable diocotron modes in hollow profiles, are studied. It is shown that low-noise techniques make it possible to follow the linear evolution and saturation of even the very weakly unstable resonant diocotron modes. DOE

MAGNETIC INSULATION OF SECONDARY ELECTRONS IN PLASMA SOURCE ION IMPLANTATION
D. J. Rej, B. P. Wood, R. J. Faehl, and H. H. Fleischmann (Cornell Univ., Ithaca, NY.) 1993 18 p Presented at the Workshop on Plasma-based Ion Implantation, Madison, WI, 4-6 Aug. 1993
(Contract W-7405-eng-36)
(DE93-040106; LA-UR-93-2950; CONF-9308156-1) Avail: CASI HC A03/MF A01

The uncontrolled loss of accelerated secondary electrons in plasma source ion implantation (PSII) can significantly reduce system efficiency and poses a potential x-ray hazard. This loss might be reduced by a magnetic field applied near the workpiece. The concept of magnetically-insulated PSII is proposed, in which secondary electrons are trapped to form a virtual cathode layer near the workpiece surface where the local electric field is essentially eliminated. Subsequent electrons that are emitted can then be re-absorbed by the workpiece. Estimates of anomalous electron transport from micro-instabilities are made. Insight into the process is gained with multi-dimensional particle-in-cell simulations. DOE

A dc PENNING SURFACE-PLASMA SOURCE
H. V. Smith, Jr., P. Allison, C. Geisik, D. R. Schmitt, J. D. Schneider, and J. E. Stelzer 1993 15 p Presented at the 5th International Conference on Ion Sources, Peking, China, 31 Aug. - 4 Sep. 1993
(Contract W-7405-eng-36)
(DE93-040126; LA-UR-93-2990; CONF-9308136-5) Avail: CASI HC A03/MF A01

After developing a pulsed-8X source for H(-) beams, we are now testing a cooled, dc version. The design dc power density on the cathode surface is 900 W/sq cm, much higher than achieved in any previously reported Penning surface-plasma source (SPS). The source is designed to accommodate dc arc power levels up to 30 kW by cooling the electrode surfaces with pressurized hot water. After striking the arc using a 600-V pulser, a 350-V dc power supply is switched in to sustain the 100-V discharge. Now our tests are concentrating on arc pulse lengths less than or equal to one second. Ultimately, the discharge will be operated dc. The source is described and the initial arc test results are presented. DOE

(DE93-019004; GA-A-21342; CONF-930655-1) Avail: CASI HC A03/MF A01

Advanced tokamak performance has been demonstrated in the DIII-D tokamak in a series of experiments which brought together developments in technology and improved understanding of the physical principles underlying tokamak operation. The achievement of greatly improved confinement coupled with development of new systems for real time plasma control have permitted investigation of the heretofore hidden or poorly controlled variables which together determine global confinement. These experiments, which included work in transport and control of the plasma boundary, point toward development of operationally and economically attractive reactors based on the tokamak. Some of these experiments are described. DOE

For the past several years, it has been evident that the very old MODCOMP 16-bit computers being used at D3-D for control and data acquisition were no longer adequate to perform the services needed. In early 1992, the computer systems group began to look seriously into alternate systems to replace these aged MODCOMP systems. The decision was made to investigate 'OPEN' system computers and also to maintain the compatibility with the large usage of CAMAC equipment as the real-time hardware interface. Information about the needs for real-time capabilities and OPEN systems ability to meet these needs is discussed. The needs include hardware requirements, operating system software which has known response rates, and interconnectability and access of data from other workstations and computers. Some of the parameters and pitfalls of open systems are discussed as well as the advantages of OPEN systems for use in a real-time environment. The success of arriving at an OPEN systems solution is examined. DOE

OPACITY MEASUREMENTS IN SHOCK-GENERATED ARGON PLASMAS
D. Erskine Jul. 1993 4 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE94-001057; UCRL-JC-112349; CONF-930676-56) Avail: CASI HC A01/MF A01

Dense plasmas having uniform and constant density and temperature are generated by passage of a planar shock wave through gas. The opacity of the plasma is accurately measured versus wavelength by recording the risetime of emitted light. This technique is applicable to a wide variety of species and plasma conditions. Initial experiments in argon have produced plasmas with 2 eV temperatures, 0.004-0.04 g/cu cm densities, and coupling parameters Gamma approximately equal to 0.3-0.7. Measurements in visible light are compared with calculations using the HOPE code. An interesting peak in the capacity at 400 nm is observed for the first time and is identified with the 4s-5p transition in excited neutral argon atoms. DOE

CONTINUUM DAMPING OF IDEAL TOROIDAL ALFVEN EIGENMODES
X.-D. Zhang, Y.-Z. Zhang, and S. M. Mahajan Aug. 1993 30 p
(Contract DE-FG05-80ET-53088)
(DE94-001233; DOE/ET-53088/621; IFSR-621) Avail: CASI HC A03/MF A01

A perturbation theory based on the two dimensional ballooning transform is systematically developed for ideal toroidal Alfven eigenmodes (TAE's). A formula, similar to the Fermi golden rule for decaying systems in quantum mechanics, is derived for the continuum damping rate of the TAE; the decay (damping) rate is expressed explicitly in terms of the coupling of the TAE to the continuum spectrum. Numerical results are compared with previous calculations. It is found that in some narrow intervals of the parameter m(circumflex epsilon) the damping rate varies very rapidly. These regions correspond precisely to the root missing intervals of the numerical solution by Rosenbluth et al. DOE

KINETIC RESONANCE DAMPING RATE OF THE TOROIDAL ION TEMPERATURE GRADIENT MODE
J. Y. Kim, Y. Kishimoto, W. Horton, and T. Tajima Sep. 1993 35 p
(Contract DE-FG05-80ET-53088)
(DE94-001234; DOE/ET-53088/623; IFSR-623) Avail: CASI HC A03/MF A01

The linear damping rates of the toroidal ion temperature gradient (eta(sub i)) mode due to the toroidal resonance are calculated in the local kinetic limit. The well-known Landau contour method is generalized to treat the analytic continuation problem of the guiding center dispersion function in the toroidal resonance system where the resonance occurs from both the magnetic Delta B-curvature drift and the parallel ion transit drift. A detailed numerical analysis is presented for the dependence of the damping rate of the toroidal eta(sub i) mode on various parameters such as epsilon(sub n), kappa(sub y), and the trapped electron fraction. In addition, a consideration is presented on the decay problem of the ballistic response by the phase

mixing in the toroidal system, which is directly related to the present damping problem of the wave normal modes by the toroidal resonance.

A TWO-DIMENSIONAL KINETIC MODEL OF THE SCRAPE-OFF LAYER
P. J. Catto and R. D. Hazeltine Sep. 1993 22 p
(Contracts DE-FG05-80ET-53088; DE-FG05-88ER-53267; DE-FG02-91ER-54109)
(DE94-001235; DOE/ET-53088/626; IFSR-626) Avail: CASI HC A03/MF A01

A two-dimensional (radius and poloidal angle), analytically tractable kinetic model of the ion (or energetic electron) behavior in the scrape-off layer of a limiter or divertor plasma in a tokamak is presented. The model determines the boundary conditions on the core ion density and ion temperature gradients, the power load on the limiter or divertor plates, the energy carried per particle to the walls, and the effective flux limit. The self-consistent electrostatic potential in the quasi-neutral scrape-off layer is determined by using the ion kinetic model of the layer along with a Maxwell-Boltzmann electron response that occurs because most electrons are reflected by the Debye sheaths (assumed to be infinitely thin) at the limiter or divertor plates.

FLUID SIMULATIONS OF DELTA T(SUB e)-DRIVEN TURBULENCE AND TRANSPORT IN BOUNDARY PLASMAS
X. Q. Xu 15 Dec. 1992 26 p
(Contract DE-FG03-90ER-54079)
(DE94-001304; UCB/ERL-M-92/147) Avail: CASI HC A03/MF A01

It is clear that the edge plasma plays a crucial role in global tokamak confinement. This paper is a report on simulations of a new drift wave type instability driven by the electron temperature gradient in tokamak scrape-off layers (SOL). A 2D fluid code has been developed in order to explore the anomalous transport in the boundary plasmas. The simulation consists of a set of fluid equations for the vorticity Delta(sub perpendicular)(exp 2) phi, the electron density n(sub c), and the temperature T(sub c) in a shearless plasma slab confined by a uniform, straight magnetic field B(sub z) with two divertor (or limiter) plates intercepting the magnetic field. The model has two regions separated by a magnetic separatrix: in the edge region inside the separatrix, the model is periodic along the magnetic field while in the SOL region outside the separatrix, the magnetic field is taken to be of finite length with model boundary conditions at diverter plates. The simulation results show that the observed linear instability agrees well with theory, and that a saturated state of turbulence is reached. In saturated turbulence, clear evidence of the expected long-wavelength mode penetration into the edge is seen; an inverse cascade of wave energy is observed. The simulation results also show that amplitudes of potential and the electron temperature fluctuations are somewhat above and the heat flux are somewhat below those of the simplest mixing-length estimates, and furthermore the large-scale radial structures of fluctuation quantities indicate that the cross-field transport is not diffusive. After saturation, the electron density and temperature profiles are flattened. A self-consistent simulation to determine the microturbulent SOL electron temperature profile has been done, the results of which reasonably agree with the experimental measurements.

THEORY AND SIMULATION OF PLASMA SHEATH WAVES
X. Q. Xu, G. DiPeso, V. Vahedi, and C. K. Birdsall 15 Dec. 1992 13 p
(Contract DE-FG03-90ER-54079)
(DE94-001305; UCB/ERL-M-92/148) Avail: CASI HC A03/MF A01

Sheath waves have been investigated analytically and with particle simulation for an unmagnetized two dimensional plasma slab with periodic boundary conditions in y and conducting walls at x = 0, L(sub x). Analytically treating the sheath as a vacuum layer, the sheath wave bears a resemblance to plasma vacuum surface waves. The simulations are in agreement with the theory for both bulk Bohm Gross waves and edge sheath waves, with some unanswered questions. Some waves that were expected did not show up, at least, where we thought they should be. Hence, improvements were made in the initialization (a better quiet start), in the diagnostics (especially the spectra in frequency), and in the excitation (ability to pulse). It has become clear that this problem, seeking both sheath (or surface) and body waves in a bounded system, needs far more attention, in analysis (non-uniform density included) and in simulation, especially in diagnostics. Hence, this report is to be treated as a start on the problem. The problem is not dropped, as the understanding of such waves (in 2D and 3D) is very important, for both basic sheath understanding and for applications, such as plasma control via excitation of sheath or pre-sheath waves.

EFFECTS OF MAGNETIC FIELD PERTURBATIONS IN THE ATF TORSATRON
R. J. Colchin, A. C. England, R. C. Isler, M. Murakami, D. A. Rasmussen, T. Uckan, J. B. Wilgen, S. C. Aceto, and J. J. Zielinski 1993 28 p
Presented at the 9th IAEA Workshop on Stellarators, Garching, Germany, 10-14 May 1993
(Contract DE-AC05-84OR-21400)
(DE94-000474; CONF-9305210-6) Avail: CASI HC A03/MF A01

The effects of errors in the magnetic fields of tokamaks on the plasma are quite different from those in stellarators. In tokamaks, field errors can cause disruptive locked modes through the nonlinear evolution of tearing modes acting on initially small error-induced islands. Scaling predictions for these effects indicate that the critical relative field error which can be tolerated becomes smaller as the tokamak size becomes larger. In stellarators, the effect is more benign, as field errors appear only to cause increased plasma transport in the vicinity of islands. Great care has been taken to minimize magnetic field errors in the most recent generation of stellarator-type magnetic plasma traps. In the past six years, several new and sensitive techniques have been developed to detect and map field errors. These methods all rely on the detection of electrons injected along magnetic field lines. During the commissioning of ATF, flux surfaces were mapped using the fluorescent screen technique. Field errors were discovered and traced to uncompensated dipoles in the helical current feeds. Prior to elimination of these errors, plasma discharges indicated centrally peaked plasma profiles. After correction of the uncompensated dipoles, flux surfaces were mapped a second time, and the island widths were found to be greatly reduced. Field errors were then deliberately introduced using a set of perturbation coils that had been added to ATF, and electron-beam mapping of the flux surfaces showed that islands several centimeters in width could easily be created by these coils. After elimination of the error fields, the measured plasma temperature and density profiles were much broader. The field-perturbation coils were then used to produce magnetic field asymmetries, and the measured plasma profiles were again shown to narrow as a result of islands.

VERIFICATION OF FREQUENCY SCALING LAWS FOR CAPACITIVE RF DISCHARGES USING TWO-DIMENSIONAL SIMULATIONS
V. Vahedi, C. K. Birdsall, M. A. Lieberman, G. DiPeso, and T. D. Rognlien 15 Dec. 1992 35 p
(Contracts DE-FG03-90ER-54079; W-7405-eng-48)
(DE94-001306; UCB/ERL-M-92/146) Avail: CASI HC A03/MF A01

Weakly ionized processing plasmas are studied in two-dimensions using a bounded particle-in-cell (PIC) simulation code with a Monte Carlo Collision (MCC) package. The MCC package models the collisions between charged and neutral particles, which are needed to obtain a self-sustained plasma and the proper electron and ion energy loss mechanisms. A two-dimensional capacitive RF discharge is investigated in detail. Simple frequency scaling laws for predicting the behavior of some plasma parameters are derived and then compared with simulation results, finding good agreements. We find that as the drive frequency increases, the sheath width decreases, and the bulk plasma becomes more uniform, leading to a reduction of the ion angular spread at the target and an improvement of ion dose uniformity at the driven electrode.

ELECTRON TEMPERATURE GRADIENT DRIVEN INSTABILITY IN THE TOKAMAK BOUNDARY PLASMA
X. Q. Xu, M. N. Rosenbluth, and P. H. Diamond 15 Dec. 1992 24 p
(Contracts DE-FG03-90ER-54079; DE-FG03-88ER-53275)
(DE94-001307; UCB/ERL-M-92/145) Avail: CASI HC A03/MF A01

A general method is developed for calculating boundary plasma fluctuations across a magnetic separatrix in a tokamak with a divertor or a

limiter. The slab model, which assumes a periodic plasma in the edge reaching the divertor or limiter plate in the scrape-off layer (SOL), should provide a good estimate, if the radial extent of the fluctuation quantities across the separatrix to the edge is small compared to that given by finite particle banana orbit. The Laplace transform is used for solving the initial value problem. The electron temperature gradient (ETG) driven instability is found to grow like t(sup -1/2)e(sup (gamma)mt). DOE

FOURTH INTERNATIONAL TOKI CONFERENCE ON PLASMA PHYSICS AND CONTROLLED NUCLEAR FUSION
H. T. Duc Guyenne, ed. and James J. Hunt, ed. Noordwijk, Netherlands May 1993 381 p The Satio Hayakawa Memorial Conference held in Toki, Japan, 17-20 Nov. 1992; sponsored by National Inst. for Fusion Science, Toki City, Fusion Science Association, and International School of Plasma Physics
(ESA-SP-351; ISBN-92-9092-246-X; ETN-94-94861) Copyright Avail: CASI HC A17/MF A03

The aim of the conference was to bring together the fusion, space and astro plasma physics. The main subjects are discussed: driven reconnection, turbulization of free shear flows, fusion plasmas, astrophysical plasmas, solar plasmas, planetary magnetosphere, dense plasmas, X-ray sources, gamma ray sources, relativistic plasmas, laboratory and space plasmas, and magnetohydrodynamic phenomena in star forming processes. For individual titles, see N94-22625 through N94-22701.

DRIVEN RECONNECTION AND SELF-ORGANIZATION
Tetsuya Sato, R. Horiuchi, T. Hayashi, K. Watanabe, and Kanya Kusano (Hiroshima Univ., Japan.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 17-2 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The physical background and significance of magnetic reconnection are given. Magnetohydrodynamic self organization process is explained. Magnetic reconnection is believed to play a very important role in fusion, space and astronomical plasmas. Particular attention is paid to magnetic reconnection driven by a converging plasma flow which is called 'driven reconnection'. Magnetohydrodynamic self organization process is described where an ordered magnetic structure is created by changing the global magnetic topology and relaxing the magnetic energy in the magnetohydrodynamic time scale. TURBULIZATION OF FREE SHEAR FLOWS: 3D PERTURBATIONS
G. D. Chagelishvili, R. G. Chanishvili, Jumber G. Lominadze, and I. N. Segal *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 23-3 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

A theory of free smooth shear flows turbulization, that may be applied to other flows turbulized by finite amplitude perturbations, is proposed. Analytical calculations are performed for three dimensional perturbations. The proposed turbulization scenario is based on the specific evolution of the linear and nonlinear processes and it is an alternative to the Landau turbulization scenario. The mathematical formalism of the problem under examination is presented, together with analysis of the drift of the disturbance spatial Fourier harmonics in the space of the wave numbers. A case of two dimensional disturbances is discussed in order to expose the physics of the energy exchange between the main flow and disturbances at the linear stage in a free Couette flow. An analysis of the evolution of three dimensional disturbances is given. ESA

Several magnetically confined toroidal plasmas for developing a fusion reactor core are explained. Magnetohydrodynamic (MHD) equilibrium and stability theory is discussed, and MHD instabilities are characterized according to the free energy source. Several well known observations of MHD instabilities in tokamaks and helical systems are discussed, associated with theoretical models. Sawtooth oscillations are the most typical phenomena commonly observed in tokamaks. Recently the similar sawtooth type oscillations were observed in Heliotron E. The latter is a new phenomenon driven by pressure gradient. MHD phenomena induced by high energy ions are fishbone oscillations and TAE (Toroidal Alfven Eigenmode) in tokamaks. Recently loss of high energy particles induced by the sawtooth oscillations are also observed in Heliotron E. Future direction of MHD studies in fusion plasma research is mentioned. ESA

PHYSICS OF TRANSPORT PHENOMENA IN MAGNETIC CONFINEMENT PLASMAS
Kimitaka Itoh, Sanae-I. Itoh (Kyushu Univ., Fukuoka, Japan.), and Atsushi Fukuyama (Okayama Univ., Japan.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 41-4 Sponsored in part by Ministry of Education (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

The phenomena caused by the transport of the plasma across the magnetic filed in toroidal devices are surveyed, and theoretical models are reviewed. The plasma structure in a steady state is discussed. The recent development of the theory on the plasma transport driven by the microscopic turbulence is explained. The sudden change in confinement, such as the H-mode transition in tokamaks, is discussed. The physics of the bifurcation of the edge plasma, based on the dynamics of the radial electric field, is studied. The role of the anomalous transport on the disruptive phenomena is reviewed. ESA

PLASMA HEATING IN TOROIDAL SYSTEMS
Masao Okamoto *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 47-5 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

The present status of plasma heating in toroidal systems, for astrophysical plasma scientists, is reviewed. The main method of plasma heating in toroidal systems or tori is to utilize fast ions. The maximum ion temperature of 38 keV was achieved at the plasma center by Neutral Beam Injections (NBI's) in the JT-60U tokamak. Ripple trapped losses of fast ions produced by NBI's were measured also in the JT-60U. The first tokamak discharges in deuterium-tritium fuelled mixtures were carried out successfully in the Jet European Torus (JET) tokamak. These experimental results are compared with the theoretical predictions based on the Coulomb collisions. The recent NBI experiments and the results are compared with theoretical predictions based on Coulomb collisions. Related to plasma heatings the current drive are discussed placing an emphasis on the neoclassical current (bootstrap current). ESA

Rosat is a German, U.S., United Kingdom project carrying a satellite borne X-ray telescope launched on 1 June 1990. One of the principal aims of the mission was to conduct a deep sky survey in the soft X-ray band. This was performed by scanning the sky in great circles in a plane perpendicular to the solar direction. The satellite carries two powerful coaligned grazing incidence telescopes observing in parallel in the soft X-ray and extreme ultraviolet bands. The X-ray telescope is equipped with position sensitive proportional counters and a channel plate detector while the extreme ultraviolet telescope, called wide field camera, has two redundant channel plate detectors in the focal plane. Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 67-7 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

Some aspects of jet dynamics in connection with radiative effects are reviewed. Examples of the study of plasma physics of relativistic jets from Active Galactic Nuclei (AGN) are discussed. The common morphologies of jets at different scales can be summarized as follows: jets are collimated over very large distances, with aspect ratios up to 100; collimation begins in the very center of the associated AGN; jets remain collimated and dynamically stable even when there are signs of interaction with external environment and sharp bends; strong evidence exists that in many cases jets are relativistic, especially in the region near the core; correlation between jets and the optical activity of the associated galactic nucleus was found. An important fact for jets from active galactic nuclei, is that dynamics and radiation emission are combined in a peculiar way: the emission is just a tiny fraction of the total energy of the flow that is estimated by assuming that the general structure is produced by the central object, either continuously or in a single outburst. This means that the dynamics must be reconstructed observing its partial transformation in radiation. ESA

CONSEQUENCES OF CHAOTIC PARTICLE MOTION FOR THE STABILITY OF SPACE PLASMA CURRENT SHEETS
Joerg Buechner and Antonius Otto (Alaska Univ., Fairbanks.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 105-110 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

The influence of a transition of thermal electrons to chaos and quasi adiabaticity on the large scale stability properties of collisionless plasma current sheets is investigated. A hybrid model which describes large scale plasma and field dynamics by a set of Magnetohydrodynamic (MHD) equations is developed, the non adiabatic response of particles in the neutral sheet is considered kinetically. Using the microscopic theory of chaotic particle motion the MHD is modified. The stability properties of two dimensional current sheet equilibria if the chaos parameter k(sub e) becomes unity are investigated. It is shown that even if electrons become chaotic the growth time of a collisionless tearing mode instability of thick current sheets is too large in order to explain substorm expansions in the Earth's magnetospheric tail. Critical thinning of the sheet is shown to lead to a quickly growing instability. ESA

ACCRETION DISKS IN BRIGHT X RAY BINARIES **c89**
Hajime Inoue *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 125-130 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

X-ray observations of low mass X-ray binaries and black hole candidates are reviewed. In these sources, an accretion disk is considered to extend close to a neutron star or a black hole and to mainly govern the appearance of the X-ray emission. These sources show soft and hard spectral states, which possibly correspond to two interchangeable states of the inner part of the accretion disk. Similarities of active galactic nuclei to black hole candidates are discussed. X-ray observations of bright X-ray binaries in which an accretion disk is considered to extend close to the surface of the compact star are reported. Hereafter, X-ray binaries including a weakly magnetized neutron star are termed low mass X-ray binaries since they are the large majority of the bright low mass X-ray binaries. ESA

THERMAL PROPERTIES AND RADIATION PROCESSES IN ASTROPHYSICAL PLASMAS
Kuniaki Masai *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 131-136 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

Thermal properties of astrophysical plasmas are discussed in view of atomic processes responsible for thermal emission. The collisional ionization process in heating/recombining is described and a characteristic time scale for a plasma to reach an ionization equilibrium is derived. The case of shock heating by the interactions of supersonic stellar winds or supernovae with the ambient matter is considered. The case of ultraviolet or X-ray irradiated plasma is presented as examples of recombining condition. The effect of ionizing/recombining condition on iron K-line emission processes is described. The difference from a plasma nearly in an ionization equilibrium as in the case of solar flare or magneto confined plasmas is important for understanding the thermal properties of astrophysical plasmas or background physics. Thermal properties of various X-ray sources in view of emission processes are summarized. ESA

Copyright Avail: CASI HC A01/MF A03

As the most promising model for the x-ray emission from a class of active galactic nuclei, represented by radio quiet quasars and Seyfert nuclei, a nonthermal pair cascade model, where soft photons are Comptonized by non thermal electron positron pair plasmas produced by gamma rays, is introduced. The simplest model of this kind, the 'homogeneous spherical cascade model', is presented. Many characteristics of this model are qualitatively similar to the homogeneous cascade model. An important difference is that gamma ray depletion is much more efficient in the surface cascade, and consequently this model satisfies the severe observational constraint imposed by the gamma ray background radiation. ESA

DARK MATTER: NEUTRON STAR HALO AND THE NATURE OF GAMMA-BURSTS **c90**
Alexander V. Gurevich, Vasily S. Beskin, Kirill P. Zybin, and Mikhail O. Ptitsyn *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 151-154 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

It is shown, that dark matter forms a halo around the Galaxy, with a power law density distribution rho = k/r(exp alpha). The size of the halo and the moment of its formation are respectively estimated to be R = 300 + 400 kpc and z = 4 + 5. The same halo is formed by relic neutron stars occurring in the protogalaxy as a result of supernova bursts which cause a change in the original chemical composition. The second component of the neutron stars which were born in the galactic disk and were pulsars at the early stage of their evolution, occurs much later. The statistical distribution of gamma bursts determined by both neutron star components is shown to be in good agreement with observations. A method of direct verificatcn of the model is proposed. ESA

GENERAL RELATIVISTIC WINDS IN A BLACK HOLE MAGNETOSPHERE **c90**
Akira Tomimatsu *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 157-160 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

Black hole driven magnetized winds in a stationary and axisymmetric magnestosphere are studied. Ingoing and outgoing winds are injected from a particle creation region around the black hole. This region is assumed to be a thin shell with a large poloidal current density. By using Ohm's law, the production of the mass flux and the heat flow is evaluated as a process of the Joule dissipation. A review of the well known results for the axisymmetric, stationary ideal magnetohydrodynamic system is given. The general relativistic effect becomes very important for ingoing winds near the black hole. The total energy carried by ingoing magnetized winds is found to be negative. This is a mechanism of energy extraction from a rotating hole. The particle creation region is considered to see the pair production of ingoing winds with negative energy and outgoing winds with positive energy. ESA

VERTICAL STRUCTURE OF ACCRETION DISKS **c90**
Toshiya Shimura and Fumio Takahara *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 161-164 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

Observationally, some active galactic nuclei show soft x-ray excess which suggests that spectrum deviates from black body. Attempts in calculating the emission spectrum for optically thick disk were made. Most investigations to date were made by adopting the given vertical structure which is obtained by assuming that radiation pressure dominates over gas pressure. However, this seems to be inadequate, because the effect of gas pressure is expected to be significant in determining the vertical structure near the surface where emission spectrum is formed. A detailed calculation, where radiative transfer and vertical structure are self-consistently solved, is performed. ESA

RELATIVISTICALLY EXPANDING PAIR PLASMAS AS BURSTING SOURCES OF COSMIC GAMMA RAYS **c93**
Peter Meszaros and M. J. Rees (Cambridge Univ., England.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 165-168 (For primary document see N94-22624 05-75)
(Grant NAGw-1522)
Copyright Avail: CASI HC A01/MF A03

High temperature shock heating of relativistically expanding plasmas produced in neutron star binary mergers provides a model for cosmic gamma ray burst sources. This requires the fireball resulting from the merger to have a very high entropy per baryon, mechanisms for which are discussed. The energy, temporal structure and spectrum produced by the blast wave and reverse shock as the fireball is decelerated in an external medium are comparable to those observed, as is the frequency of occurrence and the characteristics of the spatial distribution of the events. Difficulties common to all cosmological gamma ray burst scenarios concern the total amount of energy ultimately appearing at gamma ray energies, the time scales, the spectrum, and the great variety of time profiles. A very general mechanism which overcomes these problems is presented. Situations where the pair plasma is created in regions which are relatively free of baryons are discussed. The effect of the interaction of the expanding fireball with the external medium is considered. ESA

LABORATORY RELATIONS BETWEEN THE SOLAR WIND DYNAMIC PRESSURE AND THE MAGNETOSPHERIC STRUCTURES OF THE EARTH AND COMETS **c92**
Shigeyuki Minami, T. Saito (Tohoku Univ., Sendai, Japan.), H. U. Rahman (California Univ., Riverside.), and R. S. White (California Univ., Riverside.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 171-176 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A02/MF A03

Based on laboratory simulation of the Earth's and cometary magnetospheres, it is shown quantitatively how these configurations are controlled by the solar wind dynamic pressure without any effects of parameters. Laboratory relations between the size of contact surface of both magnetospheres and the dynamic pressure of the solar wind are analyzed and compared with the values calculated by a pressure balance equations. The quantitative result shows the dynamic pressure dependence on the size of the magnetopause. This result is applied to explain how the field lines change during the passage of the discontinuity of the dynamic pressure of the solar wind. The shrinking of the Earth's magnetosphere increases the current density in the tail and a reconnection in the tail occurs. It is suggested that this mechanism can exist even in the cometary tails resulting from the disconnection event. An evident chronological series of the solar terrestrial events of the cometary disconnection and the Earth's magnetospheric substorm due to single solar flare event is shown. ESA

LABORATORY STRUCTURE OF THE HELIOPAUSE **c92**
Shigeyuki Minami *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 177-179 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The size and structure of the heliopause, which is the hypothesized boundary separating the antiflowing solar wind from the interstellar medium, is discussed. The results of laboratory simulations found the existence of such a boundary as a highly asymmetrical and open structure not yet predicted. The heliopause is produced as a collisionless interaction between the supersonic plasma flow and another supersonic magnetized plasma flow flowing relative to the solar system. Earlier, a laboratory simulation of a cometary magnetosphere produced as an interaction between the solar wind plasma flow and a subsonic plasma flow was performed. Heliosphere is formed as a collisionless interaction between the magnetized plasma flow and the other supersonic plasma flow. ESA

THEORY OF LEAKED AURORAL KILOMETRIC RADIATION **c93**
Maria Virginia Alves, Sergio R. Lopes, and Abraham C.-L. Chian (Cambridge Univ., England.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 181-183 Sponsored by FAPESP; CNPq; and Commission of the European Communities (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

A variety of high frequency electromagnetic modes were observed in connection with the auroral kilometric radiation: extraordinary, ordinary, Z, and whistler mode. Large amplitude Langmuir, and Alfven waves are observed in the auroral region. The nonlinear decay process Langmuir to Whistler + Alfven is presented as a candidate to generate downward propagating auroral kilometric radiation along the auroral magnetic field lines, detected by satellites and rockets as well as on the ground level. Explicit expressions for the growth rate and threshold are obtained analytically. The relevance of this nonlinear wave-wave interaction process in the auroral plasma is discussed. ESA

Results from numerical simulations of the evolution of nonlinear waves and compressible Magnetohydrodynamic (MHD) turbulence in the solar wind are presented. The basic properties of the background flow, namely the solar wind expansion are taken into account. The evolution of a plasma parcel in a comoving frame of reference is studied. The main features of the expansion may be introduced in a cartesian geometry with periodic boundary conditions by expanding the equations in a small parameter, the angular dimensions of the box as viewed from the Sun. The box is seen to expand in the plane normal to the radial direction and the expansion is followed by using stretched coordinates in this plane. The expansion naturally introduces an anisotropic damping effect on velocity and magnetic field, as well as the Parker like rotation of the average magnetic fied. It is shown how this affects the evolution of an initially circularly polarized large amplitude Alfven wave in oblique propagation. Results for evolution in two dimensions and their relevance to solar wind in situ measurements are discussed. ESA

A two dimensional magnetohydrodynamic simulation of the Kelvin-Helmholtz instability at the terrestrial magnetospheric boundary was performed. The results show that finite thick velocity shear layer with super Alfvenic velocity jump at the magnetospheric boundary is unstable no matter how large the magnetosheath sonic Mach number. For all magnetosheath sonic Mach numbers, a velocity boundary layer is formed inside of the magnetospheric boundary due to tangential stress associated with the instability and a flow vortex is excited at the inner edge of the velocity boundary layer. The magnetospheric boundary is more highly nonlinearly corrugated by the instability for a smaller sonic Mach number. Tangential stress due to the instability at the boundary is mainly caused by Reynolds stress and is found to be large enough for exciting a residual plasma convection inside the terrestrial magnetosphere. An extension of the release of energy at Alfvenic fronts is presented. The Alfvenic fronts are created by the sudden switch on of a resistance, uniform across the flux tube, which is used to model the flare kernel. At

the fronts the current flowing in the flux tube is partially deflected to the surface of the tube, forming a singular surface current. In the models presented, the current density is partially deflected from smaller to larger radii within the flux tube, removing the singular surface current. It is found that for a significant amount of power released, the effective resistivity peaks in a thin sheath on the surface of the flux tube where the current drops to zero. The results show that various flare phenomena due to precipitating nonthermal electrons, accelerated in the regions of high resistivity, will be offset from the regions of peak vertical current density. Time dependent Bragg crystal spectrometer x-ray spectra of Fe XXV and S XV during the flare of 21 Jan. 1992 from Yohkoh satellite are presented. The electron temperatures are derived from the intensity ratio of the dielectronic satellite lines to the resonance line from the spectra accumulated from one minute. The ion abundance ratios, n(Li)/n(He), n(Be)/n(He) and n(B)/n(He) of iron ions and n(H)/n(He) and n(Li)/n(He) of sulphur ions are obtained from the intensity ratios of the inner shell excited satellite lines to the resonance line. The electron temperatures derived from S XV begin to increase after the rise of that from Fe XXV. The values from S XV are always lower than those from Fe XXV. The derived ion ratios show a deviation from an ionization equilibrium toward an ionizing phase except for the ratio n(H)/n(He) of sulphur ions. The accuracy of atomic data was examined. ESA

NUMERICAL SIMULATION OF MAGNETIC RECONNECTION ASSOCIATED WITH EMERGING FLUX IN THE SOLAR ATMOSPHERE c92
Takaaki Yokoyama and Kazumari Shibata (Tokyo Astronomical Observatory, Mitaka, Japan.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 203-206 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The physical process of the magnetic reconnection associated with the emerging flux is discussed. The parameter dependence of the process is studied. A numerical simulation is performed with the two dimensional magnetohydrodynamic code. A two temperature layered plasma similar to the solar photosphere/chromosphere and corona in magnetostatic equilibrium is considered. The results show that magnetic flux in the photosphere emerges by magnetic buoyancy instability as rising loops. It is found that the magnetic reconnection is more violent, when the resistivity is smaller, or when the specific heat ratio gamma is smaller. It is also found that there are four types of jet like flow associated with the reconnection: hot jet along the magnetic field lines, slingshot jet, simple island ejection,and surge like cool jet. The discovery of x-ray jet like features using the soft x-ray telescope onboard Yohkoh satellite is reported. The origin of newly discovered x-ray jets and the relation to known solar jets at other wavelengths are discussed. The jets are associated with flare like bright points, flaring emerging flux regions, or flaring active regions. They appear to recur at the same place. The following characteristics are found: in some cases, a dark void appears after ejection at the footpoint of the jet; some jets show structure which suggests a helical magnetic field configuration along the jet; one of the jets associated with a flaring bright point was found to be identified as an H alpha surge. In this case, the x-ray bright point is situated just on H alpha bright point at the footpoint of the surge. The top of the surge is not bright in x-rays. ESA

The Yohkoh gamma ray flare data obtained from the flares on 27 Oct., 15 Nov., and 3 Dec. 1991 are reported. The data was acquired with the Yohkoh gamma ray spectral observations. The 27 Oct. flare (X6.1/3B) shows a strong gamma ray line emission, while the 3 Dec. flare (X2.0/2B) shows a strong bremsstrahlung continuum extending to 10 MeV. High energy protons and ions were produced in the former flare, while electrons were preferentially accelerated in the latter flare. The line to bremsstrahlung flux ratio is variable within flares. A line feature at 420 keV was observed from the 15 Nov. flare (X1.0/3B). The following problems are discussed on the basis of the gamma ray light curves and energy spectra observed with Yohkoh: timings of electron and proton acceleration, the proton energy spectra in the 10 to 200 MeV band, the angular distribution of accelerated He nuclei, and the production of positron annhilation line at 511 keV. The behavior of test particles in a filamentary current sheet, which was proposed as a model for fragmentary energy release, is investigated. An analytic current sheet model, with antiparallel external fields, is used, and a perpendicular electric field is added. It is demonstrated that the perpendicular electric field can accelerate particles efficiently and that the multiple X-line configuration permits higher particle energies than a single X-line configuration for similar plasma parameters. Taking typical plasma parameters of impulsive flare regions in the lower solar corona, many of the observed particle characteristics can be reproduced. The relevance of the considered process to particle acceleration in galactic and extragalactic plasmas requires further study. ESA

Solar flare plasma data from the Yohkoh satellite is analyzed. The interactions of current loops were observed in the active regions on the Sun. This observation pointed out the importance of the idea that the solar flare is generated by the coalescence of current loops. The three dimensional electromagnetic particle simulations are to help in understanding the global interaction between two current loops including the evolution of the twist of loops due to instabilities. Associated rapid dynamics of current loop coalescence such as reconnection, shock waves and associated kinetic processes such as energy transfer, acceleration of particles, and electromagnetic emissions are to be studied by the code to complement analytical theories and magnetohydrodynamic simulations of the current loop coalescence. The simulation results show the strong interactions between two current loops, beam and whistler instabilities, and associated parallel and perpendicular particle heating. ESA

PROMPT HIGH-ENERGY PARTICLE ACCELERATION DURING TWO CURRENT LOOPS COLLISION **c92**
Jie Zhao, Bidzina Chargeishvili, and Jun-Ichi Sakai *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 233-236 (For primary document see N94-22624 05-75)
(Grant ASR-ME-03640247)
Copyright Avail: CASI HC A01/MF A03

A model of prompt high energy particle acceleration during two current loops collision is presented. A test of proton motion and a test of electron motion in the electromagnetic field derived from the magnetohydrodynamic equations is investigated. It is found that high energy particle acceleration occurs only in the case of Y type loop-loop collisions. The results are in strong dependence on plasma beta and initial position of the test particle. When plasma beta increases, the particle acceleration rate decreases. The particles near the edge of the collision region can be accelerated to higher energy than the ones inside it. It is shown that both the proton and electron can be maximally accelerated to approximately 10 GeV within 0.001 s and approximately 5 MeV within 0.000001 s respectively. In the case of Y type loop-loop collision, it may be expected that high energy gamma ray and neutrons will be generated under interaction between high energy particles and low atmospheric plasma. Copyright Avail: CASI HC A01/MF A03

A numerical simulation of fast magnetosonic shock wave formation during a two current loop collision is proposed. The magnetohydrodynamical model is used. It is shown that the rarefaction waves are generated in the initial stage when the two current loops start to collide. After the rarefaction waves propagate away from the exciting region, the fast magnetosonic waves with density enhancement can be produced for the case where the current strength of the loop is weak. When the current becomes strong enough, the magnetosonic shock waves can be generated in the direction perpendicular to that of two loops collision. ESA

DYNAMICS OF PHYSICAL STATE DURING TWO CURRENT LOOPS COLLISION **c92**
Bidzina Chargeishvili (Abastumani Astrophysical Observatory, Georgia, USSR.), Jie Zhao, and Jun-Ichi Sakai *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 241-244 (For primary document see N94-22624 05-75)
(Grant ASR-ME-03640247)
Copyright Avail: CASI HC A01/MF A03

A model of the two current loops collision to explain the impulsive nature of solar flares is presented. From magnetohydrodynamic equations considering the gravity and resistivity effects, self consistent expressions and equations governing a behavior of all physical quantities just after a magnetic reconnection has taken place are found. Numerical simulations revealed that the most important parameters of the problem are the plasma beta and a ratio of initial values of pressure gradient in longitudinal and radial directions. Low plasma beta case during a Y type interaction shows a rapid pinch and simultaneous enhancement of all physical quantities. Plasma beta increase causes a weakening of pinch effect and decrease of extreme values of all physical quantities. For an X type collision, the increase of the plasma beta causes high velocity jet. For I type collision it shows neither jet production nor very strong enhancement of physical quantities. Direct and oblique collisions are considered taking into account both cases of partial and complete reconnection. ESA

PLASMA STRUCTURE IN A PLASMA FLOW ALONG A MAGNETIC MIRROR FIELD
Seiji Ishiguro, Y. Kishi, and N. Sato *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 245-248 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

Using a two and a half dimensional electrostatic particle simulation code, the plasma structure in a plasma flow along a magnetic mirror field was investigated. A high speed plasma flow is injected along converging magnetic field lines. The plasma potential and density increase in the region of the converging magnetic field lines. The potential difference is greater than the ratio between the injected electron temperature and the electronic charge. The potential difference increases as the mirror ratio or the plasma flow speed increases and is accompanied by a gradual saturation. Twin potential peaks are generated at the edges of plasma flow in the region of the converging magnetic field lines. The peak potentials also increase as the mirror ratio or the plasma flow speed increases. Their positions move to the strong magnetic field region with an increase in the plasma flow speed. ESA

DYNAMO DRIVEN BY WEAK PLASMA TURBULENCE: THE EFFECT OF DIFFERENTIAL ROTATION
Yi Tong, Abraham C.-L. Chian, and Yang Su *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 249-252 Prepared in cooperation with INPE, Sao Jose dos Campos, Brazil; Cambridge Univ., England; and Academia Sinica, Beijing, China (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The effect of differential rotation on dynamo driven weak plasma

turbulence is discussed. Under the assumption that the rotational angular speeds of the celestial bodies vary with the altitude, the solutions modified by differential rotations of celestial bodies, which is applicable to the Sun and solar like stars, are found. It is discovered that there is a close relationship between plasma turbulence waves and rotations of celestial bodies, which is the cause of generating and maintaining the magnetic field. Using p-omega dynamo theory, the effect of uniform rotation of celestial bodies was researched and found to be very important; it is the requisite condition to produce the toroidal fields in the stars. ESA

DOUBLE DIFFUSION CONVECTION IN A ROTATING SPHERICAL SHELL
Kanya Kusano, Tetsuya Sato (National Inst. for Fusion Science, Nagoya, Japan.), and Kyoji Nishikawa *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 253-254 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The nonlinear dynamics of double diffusion convection in a rotating spherical shell is investigated. The simulation is carried out for the purely thermal convection. The drifting columnar convection aligning the rotating axis appears. The double diffusion convection, where the compositional buoyancy works as well as the thermal buoyancy, is studied. It is found that the columns drift to the opposite direction of the thermal convection. The highly nonlinear property of the double diffusion convection is studied. It is revealed that the nonlinear convection is complex, and different from the prediction of the linear property. ESA

ENHANCED ABSORPTION OF p-MODES ON SUNSPOT AND PLAGE REGIONS **c92**
Barry J. LaBonte and Margarita Ryutova (Institute of Nuclear Physics, Novosibirsk, USSR.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 275-278 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

A mechanism for the enhanced absorption of p modes is presented. It is based on the idea that in sunspots the magnetic field has a fine filamentary structure. Magnetic regions on the Sun's surface are observed to absorb large fractions of the p mode (acoustic) wave power incident upon them. Strong gradients in the (perturbed) parameters of a wave propagating through such an inhomogeneous medium result in enhanced absorption of the wave power. The gradients in the wave parameters occur on the scale of the background flux tubes which is smaller than the wavelength. ESA

The mechanisms by which particles are accelerated in solar flares are investigated. To perform this task it is necessary to know the chemical composition of solar flare particles and gamma ray line emissions associated with flares. High energy quanta such as gamma rays and hard x rays are emitted in association with the acceleration of high energy protons and other nuclei in solar flares. They are called solar flare particles. Radio waves covering microwave to decametric frequencies are usually emitted from relativistic electrons. These electrons are accelerated in solar flares. The efficiency for these particles to be accelerated is shown to be dependent on the ratio of particle masses to their actual charges. ESA

Copyright Avail: CASI HC A01/MF A03

The results of simulating the solar wind-magnetosphere interaction with a three dimensional, electromagnetic (EM) particle code are presented. Hitherto such global simulations were done with magnetohydrodynamic (MHD) codes while lower dimensional particle or hybrid codes served to account for microscopic processes and such transport parameters as have to be introduced ad hoc in MHD. The kinetic model combines macroscopic and microscopic tasks. It relies only on the Maxwell curl equations and the Lorentz equation for particles. The preliminary results are for an unmagnetized solar wind plasma streaming past a dipolar magnetic field. The results show the formation of a bow shock and a magnetotail, the penetration of energetic particles into cusp and radiation belt regions, and dawn to dusk asymmetries. ESA

GAMMA RAY BURST AS A RESULT OF THE EXPLOSIVE INSTABILITY IN THE MAGNETOSPHERE OF OLD NEUTRON STAR **c93**
Y. N. Istomin and D. V. Mosyagin *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 291-295 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The radio pulsars and the gamma bursts are considered phenomena of the same nature. As a result of rotation of the magnetic field the electron-positron plasma is generated in the magnetosphere. The slowly rotating neutron star is shown to work as the accumulator of the relativistic electron-positron plasma which is trapped by the strong magnetic field in the closed region of magnetosphere. The release of the energy will be at that time when the plasma energy density becomes equal to that of magnetic field. The frequency of the burst from one star is of 10 to 100 years. This conception agrees with observation if the old neutron stars are considered to form extended halo around our Galaxy. ESA

Some properties of x ray novae, considered to contain a black hole are described. 71% of the black hole candidates belong to x ray novae. From the spectral study of these novae, at the rising phase, the appearance of hard x rays beyond 100 keV is found. The origin of these hard x rays is described. The probability that a black hole candidate is an x ray nova is shown. The observation of a component comptonized by hot electrons around the soft x ray peak indicates the existence of nonthermal energetic phenomena at the early phase of the nova activity. A model including jet phenomena is discussed. ESA

The radio emission from Supernova (SN) 1987A in Jul. 1990 is discussed. A model involving synchrotron radiation emitted by electrons undergoing diffusive acceleration at the supernova blast wave is discussed. This model involves reasonable assumptions concerning adiabatic losses and the magnetic field in the preexplosion stellar wind. The light curve and spectrum produced by a constant rate of particle injection occurring in a localized region of the shock front can be calculated from it. Observations indicate that at least two such clumps were found to date. The implications of the model and its application to the observations are discussed. ESA

The simultaneous presence of relativistic particles and 'Langmuir microstructures' in pulsar magnetospheres is discussed. They result in the emission of electromagnetic waves in three different ways: the 'Langmuir microstructures', considered as an assembly of elementary structures, have an intrinsic electromagnetic radiation; the curvature radiation of the Langmuir microstructures, represented by elementary charges moving along dipolar magnetic field lines; the acceleration of relativistic particles in interaction with 'Langmuir microstructures' may also result in electromagnetic radiation. Implications of these mechanisms for the interpretation of pulsar radio emissions are considered. ESA

STRUCTURE OF ACCRETION PLASMAS OF X RAY BINARY PULSARS IN MHD TURBULENCE **c93**
Masahiro Hoshino and Toshiaki Takeshima *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 309-312 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

The time variability of the x ray binary pulsars is discussed. It is found that the observed power spectral density of the aperiodic time variability of the x ray pulsar can be approximated by a power law spectrum which changes its slope at the coherent pulsation frequency. The indices of the observed spectra are respectively 1.4 to 2.0 above the pulsation frequency and 0 to 1.0 below the pulsation frequency. The density fluctuation spectra with inverse cascades in magnetohydrodynamic turbulence is studied. It is found that the observed x ray spectra can be interpreted as the density fluctuations in the accreting plasmas. It is shown that the structure of either disk fed or wind fed pulsar can be determined by comparing the observed x ray spectra with the theoretical density fluctuation spectra of two or three dimensional magnetohydrodynamic turbulence, respectively. The model of an axisymmetric magnetic rotator is considered in order to analyze the processes of particle acceleration in pulsar magnetosphere. The energetic losses of pulsars are shown to be transformed into the kinetic energy of the plasma on the Alfven surface of the magnetosphere. A general problem of dynamics of plasma and the structure of the magnetosphere of an axisymmetric rotator is considered. It is shown that the solution of the problem where the plasma flow continuously passes through slow, fast, and Alfven surfaces does not exist. The real flow has a discontinuity on the Alfven surface. On the outer side of the Alfven surface the azimuthal magnetic field goes to zero. A super fast magnetosound wind with power comparable with total energetic losses of the star is formed. ESA

The asymptotic structure of plasma wind is discussed. By solving the special relativistic magnetohydrodynamic (MHD) equations for transfield force balance, an analytic self consistent solution is obtained for the steady and axisymmetric magnetically driven wind in the limit of viscousless, pressureless and resistiveless plasmas. In this solution, all the field lines are asymptotically conical. The inclination angle of each field line from the equatorial plane is determined. The thin jet solution as in radio loud active galactic nuclei or the equatorial wind solution can be obtained. ESA

Numerical simulations of thermally driven winds originating in a disk round a compact object are performed. The disk is assumed to be geometrically thin, self similar under scaling in radius, and in a dynamical balance. A polytropic relation between density and pressure is assumed. Steady state solutions are obtained for appropriate boundary conditions. It is found that a cone where the density and the pressure become extremely low is formed around the rotation axis, if the disk has angular momentum. While a large portion of the flow is outgoing, gas originating in the inner disk falls into the central gravitating object. In order for the disk winds to blow, the pressure and density distributions at the disk are restricted in some range. ESA

Cold relativistic ideal magnetohydrodynamic (MHD) flows are studied in the stationary and axisymmetric magnetosphere of a rapidly rotating compact object. To obtain highly accelerated winds, MHD winds emanating from a geometrically thin disk and passing through smoothly both the Alfven and fast magnetosonic points for specified configuration of streamlines are examined. It is found that for a streamline converging toward the rotation axis the fast magnetosonic point always exists at a finite distance. For a straight configuration of streamlines the fast magnetosonic point can exist close to the Alfven point only if energy flux of a wind is sufficiently large. For a convex configuration a super fast wind solution is also possible. The solution stops at a finite distance and no solution reaches infinity. ESA

Copyright Avail: CASI HC A01/MF A03

The results of three dimensional magnetohydrodynamic numerical simulations are described. They are applied to the behavior of the jets from young stellar objects under circumstances in which the ambient large scale interstellar magnetic field is twisted helically by the rotation of protostar and the protostellar disk through which this field threads. The calculations are continued until the bow shock propagates a distance 60 times as far as the initial jet radius. The case examined involves a jet with density 100 m(sub H)/cubic cm and velocity 100 km/s. It is shown that an azimuthal field B(sub phi) of strength 70 mu G drives a helical kink instability. The growth rate of this instability is large enough that significant morphological effects are expected to be visible during the typical lifetime of a Herbig-Haro (HH) object. ESA

FRAGMENTATION OF MAGNETIZED FILAMENTARY INTERSTELLAR CLOUDS **c90**
Tomoyuki Hanawa, Fumitaka Nakamura, and Takenori Nakano (Nobeyema Solar Radio Observatory, Japan.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 341-344 (For primary document see N94-22624 05-75)
Copyright Avail: CASI HC A01/MF A03

Fragmentation of filamentary molecular clouds are calculated by one dimensional and two dimensional numerical simulations. It is shown by the two dimensional simulation that the high density clumps produced by fragmentation have different shapes depending on the magnetic field strength. When the magnetic field is weak, the high density clump is spherically symmetric. When the magnetic field is strong, a geometrically thin disk perpendicular to the axis is formed. A geometrically thin disk is unstable against further fragmentation, while a spherical cloud is not likely to fragment. Hierarchical fragmentation is expected in the case of strong magnetic fields. The one dimensional simulation showed that fragmentation propagates in a filamentary cloud. High density clumps are produced successively from one side to the other. ESA

Time variations of X rays from a black hole candidate GS1124-683 are described and compared with other black hole candidates: Cyg X-1, GX339-4, GS2023+338, and a Z source of low mass binaries: GX5-1. In GS1124-683, the following states were recognized: a high flare state, a high quiet state, a high to low transition state, and a low state. Canonical time variations of X rays were observed not only in the low state but also in the high flare state. In the high state, the X rays consist of two components: a soft disk black body component and a power law component. These two components have different power spectrum density (PSD) functions: a flat top noise and a power law noise. In the low state, the X rays consist of a power law component. This component has a harder energy spectrum and shows different and larger time variations than those of the power law components in the high state. GS2023+338 in its flare state had a different normalized PSD and harder energy spectra than GS1124-683 in its high flare state. In the low state GS2023+338 had the same X ray energy spectrum and the same normalized PSD to the other black hole candidates. ESA

Nonstationary and nonaxisymmetric perturbations of magnetohydrodynamic (MHD) accretion onto a Kerr black hole are studied. A small amplitude fluctuation of the electromagnetic field is regarded as a source of perturbations in a magnetosphere. How the plasma accretion will be affected by it along a flow line especially at the fast magnetosonic point in the short wave length limit is examined. A stationary black hole magnetosphere, in which the MHD interaction is so effective that typically ten of the fluid's rest mass energy will be transported to the magnetic field, is described. Adopting the magnetically dominated limit that the energy density of the magnetic field dominates the rest mass energy density of plasma particles, the electromagnetic perturbations are described. Using this result, it is shown that the fluid energy, angular momentum, and poloidal velocity become highly variable near the fast magnetosonic point in the magnetically dominated limit. This is because the radial variation of the meridional current becomes significant and causes large Lorentz force on the fluid. The observed short term variations of X ray emission from GBHCs (galactic black hole candidates) and/or active galactic nuclei are discussed. ESA

GENERATION AND MAINTENANCE OF BISYMMETRIC SPIRAL MAGNETIC FIELDS IN DISK GALAXIES IN DIFFERENTIAL ROTATION **c90**

Takeyasu Sawa and M. Fujimoto (Nagoya Univ., Japan.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 375-378 (For primary document see N94-22624 05-75)

Copyright Avail: CASI HC A01/MF A03

The approximate dynamo equation, which yields asymptotic solutions for the large scale bisymmetric spiral (BSS) magnetic fields rotating rigidly over a large area of the galactic disk, is derived. The vertical thickness and the dynamo strength of the gaseous disk which are necessary to generate and sustain the BSS magnetic fields is determined. The globally BSS magnetic fields which propagate over the disk as a wave without being twisted more tightly are reproduced. A poloidal field configuration is theoretically predicted in the halo around the disk, and is observed in the edge-on galaxy NGC4631. Mathematical methods for the galactic dynamo are shown to be equivalent. Those methods give different growth rates between the BSS and the axisymmetric spiral (ASS) magnetic fields in the disk. Magnetohydrodynamical excitation is discussed between the BSS magnetic fields and the two armed spiral density waves. ESA

THE RELAXED STATE AND ENTROPY PRODUCTION DUE TO THE ELECTRIC RESISTIVITY AND VISCOSITY OF PLASMA

Tomokazu Kato and Hideo Nagamori *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 379-382 (For primary document see N94-22624 05-75)

Copyright Avail: CASI HC A01/MF A03

The derivation of the relaxed state in reversed field pinch using the principle of the minimum entropy production is given. A sum of the entropy productions due to the electric resistivity and due to the viscosity of the plasma is considered. As the subsidiary conditions for the variational calculus, the helicity K and cross helicity M are taken. The F-theta curves obtained from these magnetic fields show slower decreasing functions of theta, compared with the Bessel function model. The gradient of these curves depend on the boundary values of velocity. Good agreement is obtained, provided a finite tangential relative velocity at the wall is assumed. The obtained magnetic field is expressed by a linear combination of solutions of the generalized force free equations with complex proportional constants beta, and its line of force B and current J are not exactly parallel to one another. Recent investigations suggesting that amplification and regeneration of large scale magnetic fields can result from the combined action of galactic winds and magnetic diffusion are described. Observations of polarized radio emission from spiral galaxies imply the presence of magnetic fields organized with axisymmetric or bisymmetric structure on the scale of the whole galaxy. Such fields were explained previously either as a systematic patterning of primordial fields by differential rotation or as the result of dynamo generation of large scale components from non-mirror symmetric turbulence. A model for the phenomenon based on magnetic field regeneration by the interaction between turbulent diffusion and axially and radially sheared galactic winds is summarized. ESA

SPIRAL ALFVEN INSTABILITY IN ACCRETION DISKS **c90**

Michel Tagger, R. Pellat (Ecole Polytechnique, Palaiseau, France.), and F. C. Coroniti (California Univ., Los Angeles.) *In* ESA, Fourth International Toki Conference on Plasma Physics and Controlled Nuclear Fusion May 1993 p 387-390 (For primary document see N94-22624 05-75)

Copyright Avail: CASI HC A01/MF A03

With the discovery that Alfven waves can be strongly unstable in a magnetized accretion disk, it can be expected to explain the turbulence necessary to drive accretion in these disks. The instability of non-axisymmetric Alfven waves is studied using analytical derivations and numerical simulations. An exact set of equations for the time evolution of the perturbations, giving a simple analytical result in the limit of very low beta, is derived. Using a Wentzel - Kramers - Brillouin approximation, the domain of existence and dominance of the set of modes corresponding to increasing values of n are found. A one dimensional linearized magnetohydrodynamic simulation is used to confirm these results and describe the time evolution of an initial perturbation in the disk. Pressure forces which can however be straightforwardly included are neglected. These forces are found negligible, even at high beta. ESA

Magnetohydrodynamic (MHD) accretion onto a black hole is studied. The general relativistic MHD accretion was calculated by a numerical method. By using the new method of calculation, the angular momentum of the fluid generated by the black hole which is placed in the static medium with the uniform density and the uniform magnetic field is studied. The interaction between the magnetic field and the fluid matter in the rotating space time enhances the energy for the fluid and reduces the energy for the magnetic field. The rapidly rotating black hole produces the negative energy region in the distribution of the energy density for the magnetic field. The magnetic field transports the energy and the angular momentum from the stretched horizon to the outer atmosphere. The asymmetry of the flow increases the critical Mach number: M(sub AC) much greater than one. The MHD accretion with an initially uniform magnetic field produces the peaks of the magnetic stress near the event horizon. The perturbations at the peaks grow at M(sub AC) = 30. The gas energy density perturbs the MHD flow and generates the shock waves. The shock waves generated near the horizon may produce the large amount of X ray emission. The emission mechanism of the X ray radiation from the black hole candidates is discussed with the MHD accretion model. ESA

This paper studies the dynamics of vortices in type-II superconductors from the point of view of time-dependent Ginzburg-Landau equations. The paper outlines a proof of existence, uniqueness, and regularity of strong solutions for these equations. It then derives reduced systems of ODE's governing the motion of the vortices in the asymptotic limit of large Ginzburg-Landau parameter. DOE

INVESTIGATION OF QUANTUM EFFECTS IN HETEROSTRUCTURES Final Report, Jun. 1990 - Apr. 1993
Emilio E. Mendez 20 Aug. 1993 16 p
(Contract DAAL03-90-C-0008)
(AD-A270938; ARO-27458.54-PH) Avail: CASI HC A03/MF A01

The most important results obtained are summarized. These results are: growth and characterization of a new class of III-V based diluted magnetic semiconductors; observation of one-dimensional conduction on surface channels of InAs; demonstration of Tamm states in semiconductor superlattices; realization of electric-field tunable stimulated emission; demonstration of resonant interband magnetotunneling in type II heterostructures; measurement of dynamic spin polarization in diluted magnetic semiconductor quantum wells. MATERIALS PROCESSING AND MANUFACTURING TECHNOLOGIES FOR DIAMOND SUBSTRATE MULTICHIP MODULES (DSMCM) Quarterly Technical Summary, 1 Jul. - 1 Oct. 1993
David S. Dandy 1 Oct. 1993 2 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-2002)
(AD-A271011) Avail: CASI HC A01

Portions of a detailed surface kinetics mechanism developed in collaboration with Michael Coltrin of Sandia National Laboratories to describe the growth of diamond on a (100)-(2x1) surface were refined extensively during this period. Specifically, it was discovered that the molecular mechanics program employed to calculate the thermophysical properties of the diamond structures was not parameterized for use with radical species. After discussions with the program's author (N.L. Allinger, Univ. Georgia, Athens) and extensive testing with experimentally validated compounds, MM3(92) was re-applied to the 53 unique structures present in the surface mechanism to compute the temperature-dependent quantities enthalpy, entropy, and heat capacity for each structure. These thermodynamic properties were fit to polynomials over the temperature range 298.15 less than or equal to T less than or equal to 2000 K. The full mechanism is currently being incorporated into the stagnation flow model used to examine diamond deposition. DTIC

CRYSTALLOGRAPHIC PHASE TRANSITIONS IN ACTINIDE METALS AS A FUNCTION OF PRESSURE
O. Eriksson, P. Soederlind, J. Melsen, R. Ahuja, B. Johansson (Uppsala Univ., Sweden.), J. M. Wills, and A. M. Boring 1993 37 p Presented at the 1993 Actinides, Santa Fe, NM, 19-24 Sep. 1993
(Contract W-7405-eng-36)
(DE93-040138; LA-UR-93-3086; CONF-930905-2) Avail: CASI HC A03/MF A01

The authors present first-principles calculations of the equilibrium volumes and crystal structures of the light actinides (Th-Pu). The calculated equilibrium volumes for fcc Th, bct Pu, alpha-U, and beta-Np are found to agree reasonably well with the experimental data, and when comparing the total energies of the bcc, fcc, bct, alpha-U, and beta-Np structures the authors obtain the correct crystal structures for all studied systems. Equilibrium volumes for Th-Pu, using a hypothetical fcc structure, have been calculated; although spin-orbit coupling is included in these calculations, the calculated equilibrium volume of Pu is smaller than for Np, in disagreement with experiment. Moreover, the calculated tetragonal elastic constant, C prime, is shown to be negative for bcc U, bcc Np, bcc Pu, and fcc Pu. Thus, the zero temperature calculations suggest that the bcc structure is unstable for these elements and that fcc Pu is also unstable. This is in conflict with experiment and the authors are led to the conclusion that temperature effects must be of crucial importance for stabilizing cubic structures in U, Np, and Pu. Further, as a function of decreasing volume the authors predict a crystal structure sequence fcc yields bct yields fcc in Th, a sequence alpha-U yields bct yields bcc in U, and a sequence beta-Np yields bct yields bcc in Np. Also, a sequence of transitions in Sc as a function of decreasing volume have been calculated, namely hcp yields fcc yields omega yields beta-Np yields bcc. DOE

(AD-A271007) Avail: CASI HC A12/MF A03

We summarize research by SRI International on the theory of energy-assisted epitaxy and the properties of ordered semiconductor compounds. We include our published papers, and summarize the major conclusions from our work. We also report on our first year of work on the properties of InTlSb, a proposed new long-wave infrared detector material. We include a discussion of major aspects of our work, including the advantages of this material over HgCdTe and III-V superlattice and quantum-well devices. DTIC

(AD-A271437; PL-TR-93-3007-Vol-1; AD-E201668) Avail: CASI HC A09

The following annual report encompasses eleven areas of research. The basic philosophy underpinning this work has been to develop the technology for the synthesis, storage, and handling of new high-energy density materials. The importance of performing the 'easier' heavy element chemistry as the ground work to synthesizing the more challenging and potentially more useful lighter analogs has been stressed throughout much of this work. Where possible published or about to be published work is included in this report under each of the appropriate subheadings. DTIC

THE COULOMB ANOMALY IN STRONGLY DISORDERED FILMS Final Report
Shih-Ying Hsu and J. M. Valles, Jr. 1992 3 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1344)
(AD-A271095) Avail: CASI HC A01

Electron tunneling measurements of the Coulomb anomaly in the density of states in strongly disordered quench condensed granular films are presented. The strength of this anomaly grows with increasing sheet resistance, R(sub n), at low R(sub n) but saturates at high R(sub n). We suggest that the granular morphology of these films is responsible for the saturation. Author (DTIC)

FREQUENCY DEPENDENT ELECTRICAL PROPERTIES OF MINERALS AND PARTIAL-MELTS
J. J. Roberts and J. A. Tyburczy 14 Apr. 1993 40 p Presented at the 11th Workshop on Electromagnetic Induction in the Earth, Wellington, New Zealand, 26 Aug. - 2 Sep. 1992
(Contract W-7405-eng-48)
(DE93-019918; UCRL-JC-111340-Rev-1; CONF-9208215-1-Rev-1) Avail: CASI HC A03/MF A01

Methods have been developed that utilize the electrical and magnetic properties of rocks to explore the interior of the Earth. The electrical properties of minerals are strongly dependent on temperature, composition, point defect chemistry, and frequency at which the measurements were made. Complex impedance measurements aid understanding and interpretation of single frequency electrical properties measurements. This paper reviews the frequency dependent nature of the electrical response of minerals and partial-melts, with particular attention to the mineral olivine, an important mineral in the lower crust and upper mantle. FORMATION OF COLLOIDAL Ag PRECIPITATES IN FUSED SILICA BY MeV ION IMPLANTATION
C. W. White, D. S. Zhou, R. A. Zuhr, and R. H. Magruder (Vanderbilt Univ., Nashville, TN.) Aug. 1993 7 p Presented at the International Union of Materials Research Societies on Advanced Materials, Tokyo, Japan, 31 Aug. - 4 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE93-040268; CONF-9308122-5) Avail: CASI HC A02/MF A01

The formation of Ag nanoclusters in fused silica by MeV ion implantation has been studied. Size and size distributions of nanoclusters depend on dose. These nanoclusters give rise to strong absorption at the surface plasmon wavelength. Implantation at elevated temperatures results in the segregation of implanted Ag into the very near-surface region. Volume fractions for Ag nanoclusters up to approximately 5% have been obtained by MeV implantation. DOE

QUANTUM NOISE STUDIES WITH SUPERCONDUCTING TUNNEL JUNCTION MIXERS Final Report, 15 Mar. 1990 - 14 Mar. 1993
Mark F. Bocko 14 Mar. 1993 3 p
(Grant AF-AFOSR-0231-90)
(AD-A270897; AFOSR-93-0779TR) Avail: CASI HC A02/MF A01

We have completed our theoretical and experimental investigations of the noise properties of superconducting tunnel junction (SIS) mixers operated as both a phase insensitive linear amplifier and as a phase sensitive linear amplifier. We proposed a technique by which a SIS mixer could be operated as a phase sensitive linear amplifier, i.e., the gain and noise temperature of the amplifier are a function of the phase of the incoming signal. In this technique two phase coherent local oscillators at different frequencies are combined in the mixer simultaneously so both a phase preserving and phase conjugating mixing process occur resulting in a phase sensitive mixer. GENERAL INTRODUCTION TO MICROSTRUCTURAL EVOLUTION UNDER CASCADE DAMAGE CONDITIONS
H. Wiedersich Jun. 1993 25 p Presented at the International Workshop on Time Dependence of Radiation Damage Accumulation and Its Impact on Materials Properties, Montreux, Switzerland, 14-20 Oct. 1992
(Contract W-31-109-eng-38)
(DE93-017443; ANL/MSD/CP-80216; CONF-9210398-1) Avail: CASI HC A03/MF A01

A short overview of the processes that affect the evolution of the microstructure during irradiation is given. The processes include defect production with an emphasis on the effects of the dynamic cascade events, defect clustering, irradiation-enhanced diffusion, radiation-induced segregation, phase decompositions, and phase transformations. A simple model for the description of the development of the defect microstructure in a pure metal during cascade producing irradiation is also outlined which can provide, in principle, defect fluxes required for the description of the microstructural processes such as phase decomposition and irradiation-induced precipitation. METASTABLE bcc PHASE FORMATION IN THE Nb-Cr SYSTEM
D. J. Thoma, R. B. Schwarz, J. H. Perepezko (Wisconsin Univ., Madison.), and D. H. Plantz (Coast Guard Academy, New London, CT.) 1993 14 p Presented at the 8th International Conference on Rapidly Quenched and Metastable Materials, Sendai, Japan, 22-27 Aug. 1993
(Contract W-7405-eng-36)
(DE93-018376; LA-UR-93-2500; CONF-9308140-1) Avail: CASI HC A03/MF A01

Extended metastable bcc solid solutions of Nb-X at.% Cr (X = 35, 50, 57, 77, 82, and 94) were synthesized by two-anvil splat-quenching. In addition, bcc (Nb-67 at.% Cr) was prepared by mechanically alloying mixtures

of niobium and chromium powders. The lattice parameters were measured by x-ray diffraction and the Young's moduli were measured by low-load microindentation. The composition dependence of the lattice parameters and elastic moduli show a positive deviation with respect to a rule of mixtures. During continuous heating at 15 C/min., the metastable precursor bcc phases decomposed at temperatures above 750 C to uniformly refined microstructures. DOE

PARTICLES ON SURFACES OF LASER ABLATED Y1Ba2Cu3O(7-DELTA) FILMS
X. Y. Zheng, S. Zhu, D. H. Lowndes, and R. J. Warmack 1993 7 p Presented at the 2nd International Conference on Laser Ablation: Mechanisms and Applications, Knoxville, TN, 19-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-040269; CONF-9304144-12) Avail: CASI HC A02/MF A01

Pulsed laser deposition of Y1Ba2Cu3O(7-delta) films grown at heater temperature of 720 and 800 C on SrTiO3 and MgO substrates with thickness ranging from a nominal 5 unit cells to 200 nm were studied by STM and SEM. Size and density of particles present in the films were found to depend on film thickness, growth, temperature, and substrate. STM images indicate a correlation between film growth mode and particle density: the onset of big particles comes after the growth mode changes from layer-like to island growth. DOE

INNOVATIVE ACOUSTIC TECHNIQUE FOR STUDYING NEW MATERIALS AND NEW DEVELOPMENTS IN SOLID STATE PHYSICS Annual Summary Report, 1 Nov. 1992 - 31 Oct. 1993
Julian D. Maynard 4 Oct. 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1186)
(AD-A270540) Avail: CASI HC A02

The goals of this project involve the use of innovative acoustic techniques to study new materials and new developments in solid state physics, such as effects in mesoscopic electronic systems. Major accomplishments include (1) the preparation and publication of a number of major papers and chapters in books, (2) the comparison of the anisotropy of an aluminum alloy quasicrystal with that of its cubic approximant, (3) the measurement of the elastic constants of a diamond substitute material, TiB2, (4) the measurement of an extremely low (possibly the lowest) infrared optical-absorption coefficient, (5) the measurement of the effects of disorder on the propagation of a nonlinear pulse, and (6) the acquisition of initial data in an experiment on the onset of fracture. RESEARCH ON DEFECTS AND TRANSPORT IN AMORPHOUS-SILICON-BASED SEMICONDUCTORS
E. A. Schiff, Qing Gu, and Qi. Wang Aug. 1993 14 p Prepared in cooperation with Syracuse Univ., NY
(Contract DE-AC02-83CH-10093)
(DE93-017117; NREL/TP-451-5651) Avail: CASI HC A03/MF A01

This report describes Phase 2 progress in two areas: (1) electron drift and conduction band tails in a-Si(1 - x)Ge(x):H and a-Si(1 - x)C(x):H alloys, and (2) optical bias effects on electron trapping and emission in a-Si:H. The authors completed a comprehensive study of electron drift in a-Si(1 - x)Ge(x):H alloys, including correlations of the drift parameters with 'blue' fill factor measurements and open-circuit voltages in solar cells. They began a study of electron and hole drift in a-Si(1 - x)C(x):H, but, at present, they have only confirmed that C alloying degrades the electron drift mobility in a-Si(1 - x)C(x):H. They completed a study of optical bias effects on transient photocharge measurements in a-Si:H, which clarified that optical bias effects found in earlier photocurrent transient measurements occur because deep trapping is suppressed by optical bias. DOE

PREPARATION AND PROPERTIES OF SOL-GEL DERIVED PZT THIN FILMS FOR DECOUPLING CAPACITOR APPLICATIONS
R. W. Schwartz, D. Dimos, S. J. Lockwood, and V. M. Torres 1993 12 p Presented at the International Symposium on Integrated Ferroelectrics, Colorado Springs, CO, 19-21 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018853; SAND-93-1652C; CONF-9304197-1) Avail: CASI HC A03/MF A01

The use of ceramic thin films as decoupling capacitors offers the possibility of capacitor integration within the integrated circuit (IC) package and, potentially, directly onto the IC itself. Since these configurations minimize series inductance, higher operational speeds are possible. In the present study, the authors have investigated the dielectric and leakage characteristics of sol-gel PZT films. For compositions near the morphotropic phase boundary, dielectric constants of 1000, and loss tangents of about 0.02, are observed. The current-voltage behavior of the capacitors is characterized by a non-linear response, and significant asymmetry in both the leakage and breakdown characteristics as a function of bias sign is observed. Breakdown fields for PZT 53/47 thin films are typically approximately 800 kV/cm at 25 C. The authors have also studied the effects of La and Nb dopant additions and alternate firing strategies on film leakage characteristics. Donor doping at 2 - 5 mol % lowers leakage currents by a factor of 10(exp 3). For films prepared by a multilayering approach, firing each layer to crystallization results in leakage currents that are a factor of 10(exp 2) lower than films prepared by the standard process. DOE

A NOVEL METHOD FOR CHARACTERIZING THE ELECTRICAL PRIORITIES OF LEAD ZIRCONATE TITANATE (PZT) FERROELECTRIC FILMS AND MEMORY DEVICES Ph.D. Thesis
Robert D. Pugh Oct. 1993 173 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A270463; AFIT/DS/ENP/93-06) Avail: CASI HC A08

A novel technique for determining the electrical properties of lead zirconate titanate (PZT) ferroelectric-film memory devices is reported which eliminates a major systematic error discovered in other techniques. This novel technique measures the electrical response of a ferroelectric material (device) to an electrical signal that is similar in amplitude and frequency to the signals used in digital computers. The technique also provides a method for consistently converting the measured electrical response into polarization values. The ability to consistently process the data allows researchers to accurately compare the results of different measurements and to investigate the relationship changes in the operating characteristics of a ferroelectric memory device and changes in the electrical properties of the ferroelectric material. Ferroelectric aging in a PZT film was investigated using this new technique. The results of this investigation indicated that ferroelectric aging in PZT films is similar to ferroelectric aging in many bulk ferroelectric materials. Specifically, 'effective' internal electric fields increase linearly with the logarithm of the aging time. Additionally, the investigation revealed how earlier measurement techniques motivated investigators to believe that ferroelectric-film aging was different from bulk ferroelectric aging. DTIC

Fabrication of the new high Tc superconductor materials into useable long-length wires or tapes has proven difficult, often resulting in low critical currents. The ability to measure critical currents in high Tc superconducting tapes on a local scale can be valuable for assessing the microstructure resulting from the fabrication process. This paper describes the results of research on using induced currents from a small non-contacting electromagnetic probe to determine the critical current density in high Tc tapes on a local scale. The technique forces full-field penetration into the tape locally and infers the local critical current density from the 'critical state' model for flux penetration. Difficulties encountered with the tape geometry and demagnetization effects are overcome by an analysis procedure that provides comparative measurement of the critical current density with the contacting DC transport probe method. Results for several tapes with different critical currents are discussed. DOE

ALE PROJECT Annual Report
S. M. Gates, F. J. Himpsel, S. S. Iyer, D. D. Koleske, and D. Lapiano-Smith Oct. 1993 60 p
(Contract N00014-91-C-0080)
(AD-A271080) Avail: CASI HC A04/MF A01

The general goal of this work is to identify the chemical species that are present at the surface during atomic layer epitaxy (ALE). Particularly interesting is the nature of the passivation layer that terminates the broken bonds at the semiconductor surface in the first ALE step. Likewise, we follow the removal of the passivating species in the second step by thermal decomposition, desorption, irradiation, or chemical reaction. We use mainly surface-sensitive photoelectron spectroscopy at our beam line at the National Synchrotron Light Source (NSLS) in Brookhaven. During the past year we have built a new beam line at the Advanced Light Source (ALS) in Berkeley, which will exhibit 10,000 times higher brightness than NSLS. We expect the ALS beam line to become operational late '93 or early '94. DTIC

PHOTOCHEMICALLY INDUCED TRANSFORMATIONS OF TRANSITION COMPLEXES
James E. Brown 17 May 1993 136 p
(AD-A271112; USNA-TSPR-200) Avail: CASI HC A07/MF A02

Photolysis of the dinuclear complex ((n(sup 5)-C5H5)Fe(CO)2)2 in CHCl3 results in the formation of (n(sup 5)-C5H5)Fe(CO)2Cl through intermediate 17-electron radicals of the form (n(sup 5)-C5H5)Fe(CO)2. The photolyses of the related diphosphine-bridged compounds (n(sup 5)-C5H5)Fe(CO)2-u-DPPX, where DPPX = DPPM, DPPE, and DPPP and therefore are (Ph2P)2CH2, (Ph2P)2C2H, and (Ph2P)2C3H6 respectively, are described. The synthesis and photolysis of the analogous ruthenium DPPM dimer is also described. In contrast to the behavior of the simple iron dinuclear species, the DPPM and DPPE phosphine bridged compounds undergo photolysis in CHCl3 to yield products containing formyl substituted cyclopentadienyl rings. Details of the reactions studied and product characterizations using multinuclear NMR, IR, and single crystal X-ray diffraction techniques are described. A possible mechanism for the formation of the formyl derivatives is outlined. In the synthesis and purification of ((n(sup 5)-C5H5)Ru(CO))2-u-DPPM and the attempted synthesis of the ((n(sup 5)-C5H5)Ru(CO))2-u-DPPE, two ruthenium monomers of the form (n(sup 5)-C5H5)Ru(Cl)DPPX resulted. A possible reaction pathway for the synthesis of these two monomers as byproducts in the ruthenium phosphine dimer preparation is suggested. Full structural and spectral characterizations of the monomeric compounds are included. DTIC

SPIN-POLARON THEORY OF HIGH-(Tc) SUPERCONDUCTIVITY. 1: SPIN POLARONS AND HIGH (Tc) PAIRING
R. F. Wood Jun. 1993 18 p Presented at the International Symposium on High-Tc Superconductivity and its Applications, Cairo, Egypt, 4-16 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-019196; CONF-9304191-1) Avail: CASI HC A03/MF A01

The concept of a spin polaron is introduced and contrasted with the more familiar ionic polaron picture. A brief review of aspects of ionic bipolaronic superconductivity is given with particular emphasis on the real-space pairing and true Bose condensation characteristics. The formation energy of spin polarons is then calculated in analogy with ionic polarons. The spin-flip energy of a Cu spin in an antiferromagnetically aligned CuO2 plane is discussed. It is shown that the introduction of holes into the CuO2 planes will always lead to the destruction of long-range AF ordering due to the formation of spin polarons. The pairing of two spin polarons can be expected because of the reestablishment of local (short-range) AF ordering; the magnitude of the pairing energy is estimated using a simplified model. The paper closes with a brief discussion of the formal theory of spin polarons. DOE

A GREEN FUNCTION METHOD FOR CALCULATION OF ATOMIC AND ELECTRONIC PROPERTIES OF ISOLATED ADSORBATE ATOMS Ph.D. Thesis [EINE GREEN-FUNKTIONSMETHODE ZUR BERECHNUNG ATOMARER UND ELEKTRONISCHER EIGENSCHAFTEN ISOLIERTER ADSORBATATOME]
Joerg Bormet 1992 140 p In GERMAN
(ETN-93-95055) Avail: CASI HC A07/MF A02

The calculation of the thermodynamic potential and the Hellman-Feynman forces of isolated adsorbates is theoretically described. A Green function method was used for the autoconsistent solving of the Kohn-Sham equation, assuming that the chemical potential is constant and the Fermi level of electrons is known. The system of electrons and nuclei was divided in two parts with a realistic atomic structure: the semi-infinite substrate with plane translation symmetry parallel to the surface as reference system and the adsorbate system. Provided both systems are known, all important physical quantities such as electron density, state density, and derived parameters were available. The binding geometry was estimated from the total energy calculation for the adsorbate system. Results were validated for hydrogen atom and silicon on Al(111). For the system Na/Al the nature of the binding of sodium on a metallic substrate was discussed. The binding is found to be clearly ionic for the limiting case where the surface is only poorly covered by sodium. Experimental results of raster tunnel microscopy for carbon on Al (111) were discussed in order to understand the adsorption of elements of the fourth group. ESA

OPTICALLY INDUCED ROTATION DIFFUSION IN POLYMER LIQUID CRYSTALS: PHENOMENOLOGICAL THEORY AND EXPERIMENTAL VERIFICATION Ph.D. Thesis [OPTISCH INDUZIERTE ROTATIONSDIFFUSION IN POLYMEREN FLUESSIGKRISTALLEN: PHAENOMENOLOGISCHE THEORIE UND EXPERIMENTELLE VERIFIKATION]
Richard Birenheide 1991 132 p In GERMAN
(ETN-93-95068) Avail: CASI HC A07/MF A02

The physical processes involved in the light induced change of optical axis in polymer liquid crystals during cis/trans isomerization are investigated. Photostationary systems behavior in glass solid bodies such as azobenzol is mathematically formulated. The model was based on the assumption that a molecule can change its location in space during isomerization, while thermal motions are excluded because of glass state. The model predicts variations of orientation distribution function, and therefore of the optical axis, in the case of irradiation with polarized light; a biaxial distribution after irradiation with circular polarized light was ascertained. Ultraviolet dichroitic examinations were performed to assess these results; it is shown that during light exposure the thermal relaxation of cis molecules in glass is partially suppressed. The measured time profile of the refractive index allowed grid experiments to be interpreted and material qualities as a holographic accumulator to be evaluated. ESA

CMOS GATE ARRAY CHARACTERIZATION PROCEDURES Final Report, 8 May 1991 - 31 Mar. 1993

James P. Spratt Sep. 1993 44 p
(Contract DAAL02-91-C-0053)
(AD-A269943; ARL-CR-71) Avail: CASI HC A03

Present procedures are inadequate for characterizing the radiation hardness of gate array product lines prior to personalization because the selection of circuits to be used, from among all those available in the manufacturer's circuit library, is usually uncontrolled. (Some circuits are fundamentally more radiation resistant than others.) In such cases, differences in hardness can result between different designs of the same logic function. Hardness also varies because many gate arrays feature large custom-designed megacells (e.g., microprocessors and random access memories-MicroP's and RAM's). As a result, different product lines cannot be compared equally. A characterization strategy is needed, along with standardized test vehicle(s), methodology, and conditions, so that users can make informed judgments on which gate arrays are best suited for their needs. The program described developed preferred procedures for the radiation characterization of gate arrays, including a gate array evaluation test vehicle, featuring a canary circuit, designed to define the speed versus hardness envelope of the gate array. A multiplier was chosen for this role, and a baseline multiplier architecture is suggested that could be incorporated into an existing standard evaluation circuit chip. DTIC

PHOTOELECTRON SPECTROSCOPY AT MODEL BOUNDARY SURFACES OF ENERGY CONVERTER SEMICONDUCTORS/ELECTROLYTE CONTACTS: ADSORPTION, COADSORPTION, AND TRIADSORPTION OF Br2, Na, AND H2O ON VAN DER WAALS SURFACES OF METAL CHALOCOGENIDE SEMICONDUCTORS Ph.D. Thesis
[PHOTOELEKTRONENSPEKTROSKOPIE AN MODELLGRENZFLAECHEN ENERGIEWANDELNDER HALBLEITER/ELEKTROLYT-KONTAKTE: ADSORPTION, KOADSORPTION UND TRIADSORPTION VON BR2, NA UND H2O AUF VAN-DER-WAALS-OBERFLAECHEN VON HALBLEITENDEN METALLCHALKOGENIDEN]
Thomas Mayer 1993 251 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-95063) Avail: CASI HC A12

The semiconductor/electrolyte interface is modeled in ultraviolet radiation through coadsorption of electrolyte components (Br2, Na, and H2O) on Van der Walls surfaces and analyzed by photoemission. By spectroscopy of valence band area and redox level, the line structures of substrate band adsorbate emissions, their energetic positions, and relative shifts were evaluated as a function of the adsorption mode (molecular or dissociative) and the electrical potential above the surface. It is found that Br2 does not adsorb on InSe but the reaction is activated by X-ray irradiation; in order to explain this difference, the electronic and spatial structure of substrate surfaces was discussed. It is concluded that Br2 acts on nonreactive substrates as an acceptor and increases electron affinity. It is observed that H2O molecularly adsorbs at 100K in WSe2, InSe, and GaSe; the coadsorption of Br2 and H2O shows that the acceptor character of Br2 is stronger than the donor character of H2O. ESA

SINGLE-EVENT UPSET TESTING OF THE PERFORMANCE SEMICONDUCTOR 1750A CMOS/SOS CHIP SET
James D. Kinnison 30 Sep. 1993 16 p
(Contract N00039-91-C-0001)
(AD-A271158; JHU/APL-TG-1384) Avail: CASI HC A02/MF A01

Complex computer systems in space are vulnerable to many different environmental effects. One of the most difficult problems is survival under exposure to charged-particle radiation. Microelectronic devices are particularly sensitive to single-event upset-a change in the logic state of a dynamic node or memory cell due to interaction with cosmic rays. For reliable computing in satellite systems, designers must understand the sensitivity of the computer components to single-event upset. A description of tests performed on a MILSTD 1750A compliant microprocessor and peripherals is presented, and the results are used to estimate the single-event upset rate in space for each of the devices. SYNCHROTRON X RAY DIFFRACTION ANALYSIS OF PHOTOREFRACTIVE CRYSTALS AND THEIR GRATINGS Final Report, 1 May 1990 - 30 Apr. 1993
Mark Cronin-Golomb and Gerard Fogarty 26 Jul. 1993 39 p
(Contract DAAL03-90-G-0116)
(AD-A271176; ARO-27882.1-PH) Avail: CASI HC A03/MF A01

High-resolution synchrotron x-ray diffraction imaging was used to examine the state of crystal perfection in the photorefractive ferroelectric materials barium titanate and strontium barium niobate. Ferroelectric 180 degree domains, dislocations, striations, faceted growth remnants, and other lattice features were identified. The technique was also used to image the photorefractive space charge field profile in-situ. Measurements of the field were compared with numerical simulations of the standard model of the photorefractive effect, and simulations of the x-ray image formation process. DTIC

INTERINJECTION-LOCKED QUASIOPTICAL POWER COMBINERS AND PHASED ARRAYS Final Report, 1 Feb. 1989 - 30 Jun. 1993
Karl D. Stephen 16 Aug. 1993 16 p
(Contract DAAL03-89-K-0034)
(AD-A271178; ARO-26599.7-EL) Avail: CASI HC A03/MF A01

Monolithic integration of microwave and millimeter-wave circuits means new techniques for using high-frequency devices in monolithic circuits must be developed. This report describes a series of several studies that address this need. A biasing technique for negative-resistance devices using a low-impedance lossy transmission line was found to be very useful in the design of planar oscillator circuits. This technique can be applied to monolithic circuits. Mutual impedance between elements in a quasioptical power combiner is often hard to calculate. A simple technique is described for obtaining this quantity experimentally. Power combining experiments and noise measurements involving resonant-tunneling diodes conclude the report. DTIC

NATIONAL SYNCHROTRON LIGHT SOURCE USER'S MANUAL: GUIDE TO THE VUV AND X RAY BEAMLINES
N. F. Gmuer, ed. Apr. 1993 105 p
(Contract DE-AC02-76CH-00016)
(DE93-019564; BNL-48724) Avail: CASI HC A06/MF A02

The success of the National Synchrotron Light Source is based, in large part, on the size of the user community and the diversity of the scientific and technical disciplines represented by these users. As evidence of this success, the VUV Ring has just celebrated its 10th anniversary and the X-ray Ring will do the same in 1995. In order to enhance this success, the NSLS User's Manual: Guide to the VUV and X-Ray Beamlines - Fifth Edition, is being published. This manual presents to the scientific community-at-large the current and projected architecture, capabilities, and research programs of the various VUV and X-ray beamlines. Also detailed is the research and computer equipment a general user can expect to find and use at each beamline when working at the NSLS. The manual is updated periodically in order to keep pace with the constant changes on these beamlines. DOE

NON-FERMI-LIQUID AND MULTICHANNEL KONDO PHENOMENA IN Y(1-x)U(x)Pd3 AND RELATED ALLOYS
C. L. Seaman (California Univ., San Diego, La Jolla.) and M. B. Maple (California Univ., San Diego, La Jolla.) 1993 19 p Presented at the International Conference on Strongly Correlated Electron Systems, La Jolla, CA, 16-19 Aug. 1993
(Contracts W-7405-eng-36; DE-FG03-86ER-45230)
(DE93-040135; LA-UR-93-3025; CONF-930865-6) Avail: CASI HC A03/MF A01

A brief review of experimental results which reveal non-Fermi-liquid behavior in the low temperature properties of the M(1-x)U(x)Pd3 (M = rare earth or Th) Kondo alloy system is presented. Measurements of lattice parameters, electrical resistivity, magnetic susceptibility, low temperature specific heat, and magnetic neutron scattering are compared

to predictions of the multichannel Kondo model, and are generally consistent with a two-channel spin-1/2 quadrupoler Kondo effect. Possible deviations from the model due to crystalline electric field effects, interionic interactions, disorder, and Fermi-level tuning aspects are discussed. DOE

OPTICALLY CONTROLLED CURRENT FILAMENTATION IN GaAs PHOTOCONDUCTIVE SEMICONDUCTOR SWITCHES
F. J. Zutavern, A. Baca, W. D. Helgeson, H. P. Hjalmarson, G. M. Loubriel, D. L. McLaughlin, and M. W. OMalley 1993 17 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019427; SAND-93-1629C; CONF-930616-29) Avail: CASI HC A03/MF A01

The use of focused laser beams and fiber optics to control the location and density of current filaments in GaAs photoconductive semiconductor switches (PCSS) is described in this paper. An intensified CCD camera is used to monitor the infrared photoluminescence of the filaments during fast initiation of high gain switching for several sizes of lateral GaAs PCSS (e.g. 0.5 x 5, 1 x 5, 2.5 x 5, 2 x 30, and 15 x 20 sq mm). The switches are triggered with either a focused, mode-locked, Nd:YAG laser (532 and 1064 nm) or fiber-optically coupled semiconductor laser diodes (approximately 900 nm). The dependencies of the size, location, and density of the current filaments on the optical trigger, switch voltage, and switch current will be discussed. The impact of optically controlled current filaments on device design and lifetime is emphasized. Electro-optical switching amplification is demonstrated using the high gain switching mode of GaAs (lock-on). A single semiconductor laser diode is used to trigger a small GaAs PCSS. This PCSS is used to drive a 15-element laser diode array. Both electrical and optical pulse compression, sharpening, and amplification are achieved. Estimates for electrical and optical power gains are 8000 and 750 respectively. DOE

STUDY OF POSSIBLE ENERGY UPGRADE FOR THE ALS AND MODELING OF THE REAL LATTICE FOR THE DIAGNOSIS OF LATTICE PROBLEMS
M. Meddahi and J. Bengtsson May 1993 6 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC03-76SF-00098)
(DE93-040286; LBL-33225; ESG-218; CONF-930511-393) Avail: CASI HC A02

We have studied change of expected performance of the Advanced Light Source storage ring at LBL for the (design) nominal and maximum energy of 1.5 and 1.9 GeV respectively. Furthermore, we have also studied a possible increase to 2.3 GeV by modeling the change of dynamical aperture caused by saturation of the magnets. Independently, we have also modeled the beam's trajectory at injection. Comparison with bpm data from early storage ring commissioning led to the diagnosis of a major lattice error due to a short in a quadrupole, which was rectified leading to stored beam of 60 turns. NON-FERMI LIQUID AND SPIN-GLASS BEHAVIOR OF THE Sc(1-x)U(x)Pd3 SYSTEM
D. A. Gajewski, P. Allenspach, C. L. Seaman, and M. B. Maple 1993 11 p Presented at the International Conference on Strongly Correlated Electron Systems, La Jolla, CA, 16-19 Aug. 1993
(Contracts W-7405-eng-36; DE-FG03-86ER-45230)
(DE93-040134; LA-UR-93-3024; CONF-930865-5) Avail: CASI HC A03/MF A01

Previous electrical resistivity rho(T), magnetic susceptibility chi(T), and specific heat C(T) measurements on the Y(1-x)U(x)Pd3 system have revealed Kondo behavior for 0 less than x approximately less than 0.2 and spin-glass-like behavior for 0.3 approximately less than x approximately less than 0.5. The Kondo behavior is unusual and characterized by non-Fermi liquid behavior at low temperatures T much less than T(sub K), where T(sub K) is the Kondo temperature: rho(T)/rho(0) approximately equal to 1-T/(aT(sub K)), and C(T)/T approximately equal to -(1/T(sub K))ln(T) with evidence for a finite T = 0 residual entropy S(0) = (R/2)ln(2). The authors report measurements of rho(T), chi(T), and C(T) on the Sc(1-x)U(x)Pd3 system which reveal similar Kondo, non-Fermi liquid, and spin-glass behaviors. DOE

QUARTZ/FUSED SILICA CHIP CARRIERS Final Report
15 Jan. 1992 82 p
(Contract NAS3-25870)
(NASA-CR-194154; NAS 1.26:194154) Avail: CASI HC A05/MF A01

The primary objective of this research and development effort was to develop monolithic microwave integrated circuit (MMIC) packaging which will operate efficiently at millimeter-wave frequencies. The packages incorporated fused silica as the substrate material which was selected due to its favorable electrical properties and potential performance improvement over more conventional materials for Ka-band operation. The first step towards meeting this objective is to develop a package that meets standard mechanical and thermal requirements using fused silica and to be compatible with semiconductor devices operating up to at least 44 GHz. The second step is to modify the package design and add multilayer and multicavity capacity to allow for application specific integrated circuits (ASIC's) to

control multiple phase shifters. The final step is to adapt the package design to a phased array module with integral radiating elements. The first task was a continuation of the SBIR Phase 1 work. Phase 1 identified fused silica as a viable substrate material by demonstrating various plating, machining, and adhesion properties. In Phase 2 Task 1, a package was designed and fabricated to validate these findings. Task 2 was to take the next step in packaging and fabricate a multilayer, multichip module (MCM). This package is the predecessor to the phased array module and demonstrates the ability to via fill, circuit print, laminate, and to form vertical interconnects. The final task was to build a phased array module. The radiating elements were to be incorporated into the package instead of connecting to it with wire or ribbon bonds. Derived from text

GROWTH OF ZINC SELENIDE SINGLE CRYSTALS BY PHYSICAL VAPOR TRANSPORT IN MICROGRAVITY Semiannual Progress Report, 1 Apr. - 1 Oct. 1993

Franz Rosenberger 1 Oct. 1993 8 p
(Grant NAG8-767)
(NASA-CR-194679; NAS 1.26:194679) Avail: CASI HC A02/MF A01

The goals of this research were the optimization of growth parameters for large (20 mm diameter and length) zinc selenide single crystals with low structural defect density, and the development of a 3-D numerical model for the transport rates to be expected in physical vapor transport under a given set of thermal and geometrical boundary conditions, in order to provide guidance for an advantageous conduct of the growth experiments. In the crystal growth studies, it was decided to exclusively apply the Effusive Ampoule PVT technique (EAPVT) to the growth of ZnSe. In this technique, the accumulation of transport-limiting gaseous components at the growing crystal is suppressed by continuous effusion to vacuum of part of the vapor contents. This is achieved through calibrated leaks in one of the ground joints of the ampoule. Regarding the PVT transport rates, a 3-D spectral code was modified. After introduction of the proper boundary conditions and subroutines for the composition-dependent transport properties, the code reproduced the experimentally determined transport rates for the two cases with strongest convective flux contributions to within the experimental and numerical error. MONOCRYSTALLINE GERMANIUM FILM ON SAPPHIRE Patent

David J. Godbey, inventor (to Navy) and Syed B. Qadri, inventor (to Navy) 27 Apr. 1993 4 p Filed 1 Jun. 1990
(AD-D015925; US-Patent-5,205,871; US-Patent-Appl-SN-531720;
US-Patent-Class-148-33.3) Avail: US Patent and Trademark Office

A monocrystalline germanium film is grown on a sapphire substrate with a (l 102) orientation. The substrate is first pretreated to restructure the (1102) surface plane. Typically, restructuring is accomplished by either an anneal at high temperature or ion bombardment. A monocrystalline germanium layer is grown on the pretreated surface by a vapor deposition process such as molecular beam epitaxy or chemical vapor deposition.

TRANSPORT IN MICROSTRUCTURES IN THE MICROWAVE AND MILLIMETER-WAVE REGIME Final Report, 1 Apr. 1990 - 31 Mar. 1993

Theodore B. Norris, John F. Whitaker, and Gerard A. Mourou 22 Oct. 1993 238 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0214-90)
(AD-A271875; Rept-026845-910719; AFOSR-93-0827TR) Avail: CASI HC A11

This report summarizes the work performed during a 3-year URI program on Transport in Microstructures in the Microwave and Millimeter-Wave Regime. It describes significant achievements in both basic investigations of transport physics and in applications to high-speed electronics and optoelectronics. Fundamental advances were made in measurements of transport in semiconductors under high-field conditions. A variety of ultrafast optical and optoelectronic techniques were used to perform the most comprehensive experimental study to date of the dynamics of high-field transport in semiconductors, including the first observations of the ballistic acceleration of electrons, of field-dependent velocity overshoot, and of the dynamics of impact ionization. Carrier dynamics in low-temperature-grown (LT) semiconductors and high-critical-temperature superconductors were investigated, and optimum materials growth conditions determined. The work on LT GaAs led to significant advances in high speed electronic measurement, including electro-optic network analysis up to 300 GHz bandwidth, and novel photoconductive probes with ps response, high spatial resolution, and microvolt sensitivity. LT GaAs MSM photodetectors were developed with bandwidths up to 375 GHz and both high sensitivity and large-signal capability, representing significant improvements over the prior state of the art. Novel femtosecond lasers were developed. This made possible the development of new high speed measurement techniques.

Int-Patent-Class-C30B-7/02) Avail: US Patent and Trademark Office

A method and apparatus for controlling the crystallization of protein by solvent evaporation including placing a drop of protein solution between and in contact with a pair of parallel plates and driving one of the plates toward and away from the other plate in a controlled manner to adjust the spacing between the plates is presented. The drop of solution forms a liquid cylinder having a height dependent upon the plate spacing thereby effecting the surface area available for solvent evaporation. When the spacing is close, evaporation is slow. Evaporation is increased by increasing the spacing between the plates until the breaking point of the liquid cylinder. One plate is mounted upon a fixed post while the other plate is carried by a receptacle movable relative to the post and driven by a belt driven screw drive. The temperature and humidity of the drop of protein solution are controlled by sealing the drop within the receptacle and mounting a heater and dessicant within the receptacle.

(Grant AF-AFOSR-0075-91)
(AD-A272113; AFOSR-93-0815TR) Avail: CASI HC A06/MF A02

A new class of engineered materials based on crystalline organic semiconductors grown by the ultrahigh vacuum process of organic molecular beam deposition is described. The objective of this program is to investigate these materials and the conditions which lead to ordered growth between highly lattice mismatched van der Waals crystals into novel 'quasi-epitaxial' structures. During the first year of the program, considerable progress has been made in understanding and exploiting this new class of materials. In particular, a simple model has been developed which describes the physical mechanisms underlying quasi-epitaxy. The electrical and optical properties of both single and multiple heterojunction structures grown using alternating layers of two different, lattice-mismatched organic molecules have been investigated in detail. It is found that the layers can be grown sufficiently thin (10 A) to result in exciton confinement in organic multiple quantum wells. These and other quasi-epitaxially grown structures can load to an entirely new family of optoelectronic devices with exciting new electronic and nonlinear optical characteristics. DTIC

An atomic force microscope was acquired and used to study the surface properties of polymers and ceramics. Studies of polymers included nanomachining, mechanical properties, wetting behavior of latex, and metallization. Studies of ceramics included faceting of TiO2 morphology of oxide fracture surfaces, heteroepitaxial oxide film growth, and oxidation of vanadium carbide. A prototype instrument for use in ultra-high vacuum was designed. DTIC

Theoretical principles describing the current in a Schottky diode are reviewed. The Bardeen model is applied and the theoretical electrical noise generated by this type of diode is investigated. Experimental techniques and layer characterization methods are presented. The X-ray photoelectron spectroscopy was applied to investigate the oxide growth and composition. The anodic oxides and the role of several parameters on the electric characteristics of diodes are investigated. The electric characterization of ultraviolet oxides is carried out. A model of the diode satisfying the data acquired, especially concerning noise, is described. The results show that the characteristics of a low pressure lamp are the best ones and that they can be described by a thermionic model. ESA

SURFACE TREATMENT OF InP AND CONTRIBUTION TO THE OPTIMIZATION OF THE InP(p)/InP(p) REGROWN INTERFACES GROWN BY GSMBE Ph.D. Thesis [TRAITEMENTS DE SURFACE D'INP ET CONTRIBUTION A L'OPTIMISATION DES INTERFACES DE REPRISES D'EPITAXIE INP(P)/INP(P) REALISEES PAR GSMBE]
Didier Gallet 1992 262 p In ENGLISH and FRENCH
(ECL-92-48; ETN-93-94599) Avail: CASI HC A12/MF A03

The performances of optoelectronic devices fabricated by Gas Source Molecular Beam Epitaxy (GSMBE) are critically dependent on the quality of the various interfaces of the initial vertical structure. Whereas continuously grown interfaces present very high quality, interfaces obtained after growth interruption, during which various technological processes can be performed (deposition, etching, etc.), are characterized by poor electrical properties. A carrier deletion layer is generally observed at the InP(p)/InP(p) regrown interface, on top of the mesa in laser Buried Ridge heteorostructures (BRS). The properties of regrown interfaces are closely dependent on the initial surfaces properties. Therefore, they directly depend on the surface treatment quality. In order to improve the quality of regrown interfaces, four various treatments were studied: an arsenic stabilization, a passivating sulfur treatment, an encapsulating process using oxidation, and an in situ hydrogen plasma treatment. The potentiality of each treatment was evaluated by measuring the resulting electrical interface properties. The interface electrical perturbations are induced by the presence of a strong density of interface dilectronic states which pin the interface Fermi level to a position close to the minimum of the conduction and intrinsic to InP. This density is associated to damaging bonds induced by various physicochemical perturbations (impurities, phosphorus vacancies, and structural defects) which contribute to the interface disorder by perturbating the local atomic order. ANALYSIS OF COST: CVD DIAMOND DEPOSITION Quarterly Report No. 3
1993 61 p
(Contract N00014-93-C-2044)
(AD-A271980) Avail: CASI HC A04/MF A01

IBIS Associates has updated its predictive spreadsheet models of the DC arcjet and microwave chemical vapor deposition (CVD) diamond technologies. This report presents the results obtained with the new models and revised sets of baseline inputs for diamond heat sink manufacture. The cost of producing 1,000 polished diamond wafers, 1 mm thick, is estimated in the long run to be $23.70 per square centimeter by the DC arcjet deposition technology (six inch diameter), and $8.49 per square centimeter by the microwave deposition technology (sixteen inch diameter).

Fifty-one percent of the DC arcjet cost is due to the deposition step, which consumes process gases and is capital intensive. Overall, the material cost of 31.2% and labor cost of 30.2% are significant factors in the total cost. DTIC

Avail: CASI HC A01/MF A01

Metal/insulator/semiconductor (MIS) structures were produced by reactive sputter deposition of germanium nitride onto n-GaAs. The electrical properties of the n-GaAs-germanium nitride interface were found to exhibit a strong dependence on the deposition process parameters and the annealing conditions. The interface density evaluated from conductance and capacitance measurements was on the order of 10(exp 11) /eV-sq cm at the mid gap and was improved by annealing in a hydrogen atmosphere before and after metallization. Because of a possible excess of germanium ions near the interface a counterclockwise hysteresis in the capacitance voltage curve was observed. The dependence of germanium nitride film properties on heat treatment at different temperatures in hydrogen and nitrogen gas was studied by X-ray diffraction analysis and ellipsometric measurements. The low interface state density found using low r.f. sputtering power establishes sputtering as a competitive deposition technique. Author (revised)

In this paper we show how the chemical composition of an insulating film on a semiconducting substrate can be estimated using null or fixed wavelength ellipsometry. Multiple-wavelength angle-of-incidence (MAI) ellipsometry, together with the effective medium approximation, were used to evaluate both the composition and the geometrical structure of an insulating film made of silicon nitride and silicon oxide on a GaAs substrate. The general applicability of the technique for null or fixed wavelength ellipsometers is critically assessed and compared with the more commonly used fixed-angle-of-incidence spectroscopic ellipsometric method. The maximum experimental sensitivity in ellipsometric measurements for samples that include a composite (two-layer) film on a substrate is treated with mathematical generality. A detailed theoretical computation is made for a system consisting of a moderately thick film on a substrate and including either an interface layer between the film and substrate or a thin surface layer on top of the moderately thick film. Analytical conditions for the sensitivity of p or s wave suppression are determined. For the air/SiO2/Si system a numerical calculation is performed to determine the optimum sensitivity for interfacial layer studies. Author (revised)

VARIABLE WAVELENGTH, VARIABLE ANGLE ELLIPSOMETRY INCLUDING A SENSITIVITIES CORRELATION TEST Abstract Only **c27**

George H. Bu-Abbud, N. M. Bashara, and John A. Woollam *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Thin Solid Films (Netherlands, Elsevier Sequoia), v. 138, 1986 p 27-41 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

By combining variable wavelength and variable angle of incidence to assess solutions of the optical parameters of a system, a procedure is developed which provides more information on the optical parameters than methods where either the wavelength or the angle of incidence is held constant. This results in a reduction in the interdependence of the optical parameters and provides for more acceptable solutions. For a film on a substrate structure, if one knows the substrate optical parameters, the thickness and optical properties of the film can be characterized at each wavelength without the need for a dispersion equation, an independent measurement of the thickness, or any special requirements on the substrate optical properties. For a nearly transparent film on an absorbing substrate, all four parameters of the three-medium model (the substrate and film refractive indices, substrate extinction coefficient, and film thickness) can be determined. If, in addition, one uses a dispersion relation for the refractive index in a very weakly absorbing film, the optical properties of an absorbing substrate and the film can be determined unambiguously. As a second major feature of this paper we show that the sensitivity correlation matrix as well as the traditional parameter correlation matrix, should be calculated if one is to determine the independence of ellipsometric parameter solutions. An SiO2 film on silicon is used for illustration, but of course the analysis is recommended for more complicated materials systems.

Liu *In* Nebraska Univ., Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Solid-State Electronics (England, Pergamon Journals Ltd.), v. 29, no. 9, 1986 p 933-940 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The interfacial electronic properties of diamond-like carbon on both n-InP and p-InP were studied. These measurements include conductance and capacitance versus frequency or bias voltage for metal-insulator-semiconductor structures. Carbon was deposited by both ion-beam sputtering and from an rf plasma. We find that interface electronic state densities range from 10(exp 11) to 10(exp 13) states/eV sq cm, depending on sample and preparation procedures. Normalized conductance versus frequency data show an unusual behavior, namely, two loss peaks having greatly differing voltage dependencies. We speculate on the physical origins of the two peaks. The sensitivity of spectroscopic ellipsometry data to multilayer model parameters is shown to be a strong function of the angle of incidence. A quantitative study for a GaAs-Al(x)Ga(1-x)As-GaAs structure shows that maximum sensitivity to layer thicknesses and ternary composition occurs near the wavelength-dependent principal angle. These results are verified by experimental measurements on two MBE-grown samples. Moderately high doping levels in the ternary layers are also found to strongly affect the data at photon energies below the ternary band gap. Null ellipsometry measurements at only two wavelengths are sufficient to determine layer thicknesses. Author (revised)

Avail: CASI HC A01/MF A01

Variable angle of incidence spectroscopic ellipsometry (VASE) has been implemented as a means of determining layer thickness alloy composition and growth quality of GaAs/AlGaAs samples composed of relatively thick layers as well as superlattices. The structures studied in this work contained GaAs/AlGaAs multilayers with a superlattice 'barrier' and were grown for later formation of modulation-doped field effect transistors (MODFET's). Sample modeling was performed by treating the superlattice as a bulk AlGaAs layer of unknown composition. Extremely good data fits were realized when five layer thicknesses and two alloy ratios were allowed to vary in a regression analysis. Room temperature excitonic effects associated with the e-hh(1) e-lh(1) and e-hh(2) transitions were observed in the VASE data. Author

VARIABLE ANGLE SPECTROSCOPIC ELLIPSOMETRIC CHARACTERIZATION OF SURFACE DAMAGE IN CHEMICAL-MECHANICAL POLISHED GaAs Abstract Only **c27**
Yi-Ming Xiong and Paul G. Snyder *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Thin Solid Films (Elsevier Sequoia), v. 220, 1992 p 303-310 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

Variable angle spectroscopic ellipsometry (VASE) was applied to the quantitative characterization of surface and subsurface damage in GaAs, induced by conventional chemical-mechanical (CM) polishing. We show that the optimum selection of angle of incidence (75 degrees) and spectral range (greater than or equal to 430 nm) is of crucial importance for detecting and evaluating surface and subsurface quality. The measured VASE data from 249 to 789 nm were analyzed with several fitting models. A two-layer model, with a GaAs oxide over layer on a subsurface layer on a GaAs substrate, was found consistently to yield the best fits, suggesting the presence of subsurface damage in CM polished GaAs. In the model calculations, each composite layer was assumed, in the Bruggeman effective medium approximation, to be a simple physical mixture of the chosen constituents. The fitting results indicate that, typically, the thickness values were 2-3 nm of oxide overlayer and 15-40 nm of subsurface damage beneath it, consisting of about 1 percent-2 percent reduction in density. Independent atomic force microscopy (for surface characterization) and x-ray diffraction (for subsurface characterization) measurements were also made, for comparison with the VASE results. Consistent agreement was found. Author (revised)

VARIABLE ANGLE OF INCIDENCE SPECTROSCOPIC ELLIPSOMETRIC MEASUREMENT OF THE FRANZ-KELDYSH EFFECT IN MODFET STRUCTURES Abstract Only
Paul G. Snyder, Jae E. Oh, and John A. Woollam *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Materials Research Society Symposium Proceedings, v. 77, 1987 p 761 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

It has been shown recently that variable angle-of-incidence spectroscopic ellipsometry (VASE) is a sensitive technique for determining semiconductor multilayer model parameters, e.g. layer thicknesses and ternary compositions. In this paper, we show that VASE is in addition sensitive to the Franz-Keldysh effect induced by band bending in the barrier layer of a GaAs-AlGaAs-GaAs (MODFET) structure. VASE measurements differ from electroreflectance and photoreflectance in that the internal heterojunction region electric field is directly probed without the application of a modulating field. The Franz-Keldysh effect appears in the VASE spectra near the AlGaAs band gap energy. Data for two samples with different doping profiles are quantitatively modeled to determine the internal electric field amplitudes. Author (revised)

ELLIPSOMETRIC ANALYSIS OF BUILT-IN ELECTRIC FIELDS IN SEMICONDUCTOR HETEROSTRUCTURES Abstract Only **c33**
Paul G. Snyder, Jae E. Oh, John A. Woollam, and R. E. Owens (Colorado State Univ., Fort Collins.) *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Appl. Phys. Lett. (American Inst. of Physics), v. 51, no. 10, 7 Sep. 1987 p 770 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

Measurements of Franz-Keldysh (FK) effects in GaAs-Al(x)Ga(1-x)As heterostructures by variable angle of incidence spectroscopic ellipsometry are reported. The measured FK effects are due to the built-in band bending at the surface and heterointerfaces, with no externally applied bias or modulating voltage. The polarity of the FK line shape indicates whether the field is uniform or nonuniform (inhomogeneous) in the direction along the growth axis, while the line width is determined by the peak field strength. This information can be used to characterize the doping concentration in the Al(x)Ga(1-x)As layer. Author (revised)

OPTICAL MEASUREMENT OF BUILT-IN AND APPLIED ELECTRIC FIELDS IN Al(x)Ga(1-x)As/GaAs HETEROSTRUCTURES Abstract Only **c33**
Paul G. Snyder, Kenneth G. Merkel, and John A. Woollam *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Spectroscopic Characterization Techniques for Semiconductor Technology 3 (Bellingham, WA, Society of Photo-Optical Instrumentation Engineers), v. 946, 1988 p 98 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

Variable angle spectroscopic ellipsometry (VASE) is used to study the built-in electric fields in Al(x)Ga(1-x)As/GaAs heterostructures. VASE data, obtained with no electrical contacts on the sample, contain Franz-Keldysh (FK) line shapes at the AlGaAs band gap energy, which are due to the

built-in field across the buried AlGaAs layer. Analysis of the line shapes, using the FK theory together with a multilayer model, yields the approximate field profile in the layer. This, combined with a numerical solution of Poisson's equation, provides the approximate doping concentration. In addition, measurements made on samples with electrical contacts are described.

Woollam (Nebraska Univ., Lincoln.) *In* Nebraska Univ., Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Materials Research Society Symposium Proceedings, v. 77, 1987 p 563 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The x value of the most thermally stable co-sputtered Ta(x)Cu(1-x) alloy films are found to correlate with measured maximum temperature coefficients of resistance as a function of alloy composition. To investigate the possible application of these materials as diffusion barriers for the AuGaAs system vacuum, annealing and infrared rapid thermal annealing are made over a wide temperature range. Resistivity changes, x-ray diffraction, Auger electron spectroscopy, and Rutherford backscattering measurements are performed to find the metallurgical stabilities of these materials at elevated temperatures. For high x values the reaction temperature for Ta(x)Cu(1-x) in contact with GaAs lies between 5OO and 700 C. For Au in contact with Ta(x)Cu(1-x), the Ta(x)Cu(1-x)/GaAs reaction occurs at about 600 C. Amorphous Ta93Cu7 exhibits uniform mixing with surrounding elements whereas Ta80Cu20 exhibits phase separation.

AMORPHOUS Ta-RICH Ta-Cu FILMS AS DIFFUSION BARRIERS BETWEEN Au AND GaAs Abstract Only **c27**
Jae E. Oh (Nebraska Univ., Lincoln.), John A. Woollam (Nebraska Univ., Lincoln.), John J. Pouch, Samuel A. Alterovitz, and David C. Ingram (Universal Energy Systems, Inc., Dayton, OH.) *In* Nebraska Univ., Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Journal of Vacuum Science Technology (American Vacuum Society), v. 6, no. 3, May - Jun. 1988 p 825 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The thermal stability of alloy films in the cosputtered amorphous Ta-Cu alloy systems have been found to be correlated with the measured maximum negative temperature coefficients of resistance as a function of alloy composition. From results of resistivity changes, x-ray diffraction, Auger electron spectroscopy, and Rutherford backscattering, reaction temperatures of Ta93Cu7 alloy films with Au overlayers and GaAs substrates were determined to be 600 and 700 C, respectively. Electrical measurements were performed with Schottky diodes formed on n-type GaAs. Amorphous Ta93Cu7/GaAs Schottky diodes were found to be electrically stable up to annealing temperatures of 400 C. Also rapid thermal annealing was applied to capitalize on its short processing time for possible application to self-aligned gate technology using this material.

Variable angle of incidence spectroscopic ellipsometry is a sensitive nondestructive technique for determining optical constants, layer thicknesses, microstructure and other parameters. We have applied this technique to the study of AlAs-GaAs and Al(x)Ga(1-x)As-GaAs superlattices. For a sample with Al(0.5)Ga(0.5)As barrier layers and 20 periods, sharp spectroscopic features were observed at the first electron to heavy hole, e-hh(1), first electron to light hole, e-lh(1), and second electron to heavy hole, e-hh(2) transition energies. Cross sectional transmission electron microscopy (XTEM) showed this superlattice to be of good quality. Ellipsometric data for two other samples with AlAs barriers did not contain any sharp features due to quantized level transitions and XTEM of these samples revealed poor quality superlattice structure. An advantage of ellipsometry is that the complex refractive index can be obtained without Kramers-Kronig analysis. The effective refractive index for a 20 period superlattice was solved using ellipsometric data at three angles of incidence near 74 degrees. The real part is increased by about 2 percent at the e-hh(1) peak and the imaginary part (extinction coefficient) is increased by 0.05.

Variable Angle of incidence Spectroscopic Ellipsometry (VASE) is a sensitive, nondestructive method of determining optical constants, layer thicknesses, alloy compositions and other parameters. We model the VASE data for a sample containing a 20 period Al(0.5)Ga(0.5)As-GaAs superlattice, to obtain the effective index of refraction (n) and extinction coefficient (k) of the superlattice layer. The room temperature VASE spectra contain strong, sharp features at the e-hh(1), e-lh(1) and e-hh(2) excitonic transition energies. In addition, VASE was used to characterize more complicated layered structures, which also contained superlattices.

Avail: CASI HC A01/MF A01

Variable angle of incidence spectroscopic ellipsometry (VASE) was used to determine the thickness, alloy composition, and growth quality of multilayer samples. These samples contained a single quantum well grown on a GaAs/AlGaAs superlattice. The superlattice layers were modeled as a bulk AlGaAs layer of unknown composition and thickness. A data fitting procedure allowed the variation of five layer thicknesses and two alloy compositions in a regression analysis. Extremely good data fits of the ellipsometric parameters Psi and Delta were realized in the 1.55 to 3.54 eV spectral range. Computer generations of the ellipsometric parameters were performed, and were compared with experimental results. The e-hh(1), e-lh(1), and e-hh(2) exciton transitions were observed in the VASE data measured at room temperature. VASE has thus provided a nondestructive and highly effective technique for characterizing intricate multilayered structures.

Merkel (Wright Research Development Center, Wright-Patterson AFB, OH.), and D. C. Reynolds (Wright State Univ., Dayton, OH.) *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Materials Research Society Symposium Proceedings, v. 160, 1990 p 719 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

Variable angle spectroscopic ellipsometry (VASE) was used to characterize a 20 period GaAs/Al(x)Ga(1-x)As multiple quantum well structure grown by molecular beam epitaxy. The barriers were nominally 200A. Al(.25)Ga(.75)As and the well regions were grown to approximate a linearly graded composition, from x = 0 to x = 0.25, with total well width 200 A. VASE data in the E(sub 1), E(sub 1) + Delta(sub 1) region were analyzed using four different models. It was found that the dielectric function of the cap GaAs layer was shifted to higher energy with respect to the bulk GaAs dielectric function. Author

Recent developments in normal-incidence reflection mode modulators are extended in this investigation to the design and simulation of oblique-incidence polarized light modulators. The active element in the design is a 1OOA GaAs quantum well between Al(.3)Ga(.7)As barriers. A model for the optical properties of the quantum well is developed that accounts for quantum confinement, Stark shifts, excitons, and inhomogeneous broadening. Results of a simulation for an oblique-incidence intensity modulator, with two different input polarizations, are presented.

GaAs(100) SURFACE MODIFICATIONS AT ELEVATED TEMPERATURES, STUDIED BY IN-SITU SPECTROSCOPIC ELLIPSOMETRY Abstract Only
Huade D. Yao, Paul G. Snyder, and John A. Woollam *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Materials Research Society Symposium Proceedings, v. 202, 1991 p 339 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

Spectroscopic ellipsometric (SE) measurements of GaAs (100) were carried out in an ultrahigh vacuum (UHV) chamber, without arsenic over pressure, at temperatures ranging from room temperature (RT) to approximately 610 C. Surface changes induced at elevated temperatures were monitored by in-situ spectroscopic ellipsometry. The SE data clearly displayed in real time the process of desorption of the GaAs-surface-oxide overlayer at approximately 580 C. In addition, changes in the near-surface region were observed before and after the oxide desorption. The near-subsurface region (top 50-100 A) became less optically dense after being heated to 540 C or higher. For comparison, a pre-arsenic-capped molecular-beam-epitaxy (MBE)-grown GaAs surface was also studied. After the arsenic cap was evaporated off at approximately 350 C, this surface remained smooth and clean as it was heated to higher temperatures.

ELLIPSOMETRIC STUDY OF GaAs(100) SURFACE CHANGES INDUCED AT ELEVATED TEMPERATURES Abstract Only
Huade D. Yao, Paul G. Snyder, and John A. Woollam *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Proceedings of the Second International Conference on Elec. Mats (Materials Research Society), 1990 p 501 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

GaAs (100) samples were heated to temperatures as high as approximately 610 C in an ultrahigh vacuum (UHV) chamber without arsenic overpressure. In situ spectroscopic ellipsometry (SE) was used to monitor the surface changes induced at elevated temperatures. The SE measurements clearly displayed in real time the process of desorption of the GaAs-surface-oxide layer. In addition, the character of the near-subsurface region (top 50-100 A) was observed to change, apparently becoming less dense when heated to approximately 550 C or higher. The SE data also suggest that moisture is present in and on top of the oxide layer of a sample that has been exposed to air, and that the moisture desorbs in vacuum.

TEMPERATURE DEPENDENCE OF OPTICAL PROPERTIES OF AlAs, STUDIED BY IN-SITU SPECTROSCOPIC ELLIPSOMETRY Abstract Only
Huade D. Yao, Paul G. Snyder, Kathleen Stair (Amoco Oil Co., Naperville, IL.), and Thomas Bird (Amoco Oil Co., Naperville, IL.) *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Materials Research Society Symposium Proceedings, v. 242, 1992 p 481 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The dielectric functions epsilon = epsilon(sub 1) + i(epsilon(sub 2)) of AlAs were determined from 1.5 eV to 5.0 eV, by spectroscopic ellipsometry (SE), from room temperature (RT) to approximately 577 C in an ultrahigh vacuum (UHV) chamber. Molecular beam epitaxy (MBE)-grown AlAs was covered by a thin GaAs layer, which was passivated by arsenic capping to prevent oxidation. The arsenic cap was desorbed inside the UHV chamber. SE measurements of the unoxidized sample were made at various temperatures. Temperature dependent optical constants of AlAs were obtained by mathematically removing the effects of the GaAs cap and substrate. Quantitative analyses of the variations of critical-point energies with temperature, by using the harmonic oscillator approximation (HOA), indicate that the E(sub 1) and E(sub 1) + Delta(sub 1) energies decrease approximately 350 MeV as temperature increases from RT to 500 C.

For the first time, measurements of the dielectric function of thermodynamically stable In(x)Ga(1-x)As in the composition range 0.3 less than or equal to x less than or equal to 0.7 are reported. The optically thick samples of InGaAs were made by molecular beam epitaxy (MBE) in the range 0.4 less than or equal to x less than or equal to 0.7 and by metal-organic chemical vapor deposition (MOCVD) for x = 0.3. The MBE made samples, usually 1 micron thick, were grown on semi-insulating InP and included a strain release structure. The MOCVD sample was grown on GaAs and was 2 microns thick. The dielectric functions were measured by variable angle spectroscopic ellipsometry in the range 1.55 eV to 4.4 eV. The data was analyzed assuming an optically thick InGaAs material with an oxide layer on top. The thickness of this layer was estimated by comparing our results for the InP lattice matched material, i.e. x = 0.53, with results published in the literature. The top oxide layer was removed mathematically for x = 0.3 and x = 0.53 to get the dielectric function of the bare InGaAs. In addition, the dielectric function of GaAs in vacuum, after a protective arsenic layer was removed, was measured. Our dielectric functions for x = 0, 0.3, and 0.53 were used together with the x = 1 result from the literature to evaluate an algorithm for calculating the dielectric function of InGaAs for an arbitrary value of x (0 less than or equal to x less than or equal to 1). Results of the dielectric function calculated using the algorithm were compared with experimental data. Author (revised)

Variable-angle spectroscopic ellipsometry was used to estimate the thicknesses of all layers within the optical penetration depth of InGaAs-based modulation doped field effect transistor structures. Strained and unstrained InGaAs channels were made by molecular beam epitaxy (MBE) on InP substrates and by metal-organic chemical vapor deposition on GaAs substrates. In most cases, ellipsometrically determined thicknesses were within 10 percent of the growth-calibration results. The MBE-made InGaAs strained layers showed large strain effects, indicating a probable shift in the critical points of their dielectric function toward the InP lattice-matched concentration. STUDY OF CONCENTRATION-DEPENDENT DIELECTRIC PROPERTIES OF n-TYPE GaAs USING VARIABLE ANGLE SPECTROSCOPIC ELLIPSOMETRY Abstract Only

Paul G. Snyder and Yi-Ming Xiong *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Surface and Interface Analysis, v. 18, 1992 p 107-112 (For primary document see N94-20971 05-76)

Avail: CASI HC A01/MF A01

The dielectric function epsilon spectra of Si-doped n-type GaAs crystals at room temperature (296 K) were determined between 1.53 and 5.01 eV, using variable angle spectroscopic ellipsometry (VASE). Samples with carrier concentrations ranging from 4.6 x 10(exp 17) to 3.3 x 10(exp 18) cm(sup -3) were measured. The effects of surface microscopic roughness, native oxide overlayer and the subsurface damage were mathematically removed with an appropriate multilayer model. The GaAs dielectric function spectra were modeled using the sum of seven harmonic oscillators, whose center energies, half-widths, and amplitudes were fitting parameters in the multilayer model. It was found that as the doping level increased, the E(sub 1) and E(sub 1) + Delta(sub 1), peak structures near 3 eV in the epsilon(sub 2) spectrum broadened considerably more than the E(sub 0)(sup prime) and E(sub 2) peak structures near 4.7 eV, while the amplitude of the E(sub 1) peak decreased with respect to that of the E(sub 1) + Delta(sub 1) peak. Other effects due to doping were a shift of the epsilon(sub 2) spectrum towards lower energies and a decrease in the amplitude of the E(sub 2) peak. Author (revised)

A modular spectroscopic ellipsometer, capable of both in-situ and ex-situ operation, was used to measure important growth parameters of GaAs/AlGaAs structures. The ex-situ measurements provided layer thicknesses and compositions of the grown structures. In-situ ellipsometric measurements allowed the determination of growth rates, layer thicknesses, and high temperature optical constants. By performing a regression analysis of the in-situ data in real-time, the thickness and composition of an AlGaAs layer were extracted during the molecular beam epitaxy (MBE) growth of the structure. Avail: CASI HC A01/MF A01

Noninvasive, real-time material growth monitoring is becoming increasingly important as epitaxial layer structures become more complex and the thickness and alloy composition tolerances are reduced. The technique of spectroscopic ellipsometry was adapted to a commercial III-V semiconductor molecular beam epitaxy (MBE) system to monitor layer thickness, ternary alloy composition, and substrate temperature in real time during the growth of multilayer structures. Practical system considerations for reliably implementing the rotating analyzer ellipsometer in a hydride source MBE environment that contains a high pressure of dimeric group V species is discussed. Measurement of substrate temperature from room temperature to typical growth temperatures is then presented as well as in situ determination of alloy composition and thickness for efficient growth calibration. A growth run of GaAs/AlGaAs epitaxial layers is examined to observe surface smoothing upon group III pulse deposition and growth interruption at heterointerfaces. The growth of quantum well structures is then monitored and analyzed in attempts to extract heterojunction interface abruptness. Finally, a summary of epitaxial reactor design issues that need to be addressed to implement the spectroscopic ellipsometry (SE) technique in commercial systems is provided. Author (revised)

THERMAL DIFFUSIVITY MEASUREMENTS BY PHOTOTHERMAL LASER BEAM DEFLECTION (PTD): DATA ANALYSIS USING THE LEVENBERG-MARQUARDT ALGORITHM **c36**

Hassanayn Machlab, William A. McGahan, and John A. Woollam *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Thin Solid Films (Elsevier Sequoia), v. 215, 1992 p 103-107 (For primary document see N94-20971 05-76)

Avail: CASI HC A01/MF A01

Photothermal laser beam deflection (PTD) is a powerful tool used to obtain the thermal diffusivities of bulk solids and thin films. PTD is of special interest for non-destructive evaluation of bulk, thin film, and composite materials anticipated for use in future space missions. Polycrystalline diamond thin films are expected to be useful as heat sinks and thermal conductors in space applications, and measurement of thermal diffusivity in these films is very important. One of the major problems in applying the PTD technique for diffusivity measurements (and hence the thermal conductivity, since heat capacities and densities are not difficult to measure and are frequently known) is that a numerical regression analysis must be performed to simultaneously determine several unknown parameters. Regression is done by matching experimental data with calculations based on analytic models such that an error function is minimized. The adaption of the

Levenberg-Marquardt algorithm for regression analysis to the determination of thermal diffusivity of bulk and thin film solids by PTD is described. The analytic theory is reviewed and the numerical analysis method is described. Experimental equipment for high signal-to-noise ratio data is described and data on bulk aluminum taken over a range of frequencies are presented. Regression analysis fits to the theory (performed in an inverse space reference frame) yield values for parameters of the experiment, including the thermal diffusivity. Author (revised)

THERMAL CHARACTERIZATION OF THIN FILMS BY PHOTOTHERMALLY INDUCED LASER BEAM DEFLECTION Abstract Only **c27**
Hassanayn Machlab, William A. McGahan, John A. Woollam, and Kevin Cole *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Thin Solid Films (Elsevier Sequoia), v. 224, 1993 p 22-27 Presented at the 19th International Conference on Metallurgical Coatings and Thin Films, San Diego, CA, 6-10 Apr. 1992 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The photothermal deflection technique, also known as the 'mirage effect,' is a powerful nondestructive means of evaluating the thermal properties of both bulk materials and thin films. In this experiment, the sample is heated by a modulated laser beam, and the deflection of a second laser beam passing through the heated region above the sample (parallel to the surface of the sample) is measured as a function of distance between the probe and heating beams. The temperature profile above the sample, and hence the beam deflections, are determined by the sample properties. These measurements can be analyzed to determine the thermal diffusivity of the sample. For multilayered samples it is often possible to find the thermal constants for a single layer if the properties of the other materials in the sample are previously measured or otherwise known. The authors have nonlinear regression software for the analysis of samples that may have any number of layers, based on a Green's function formalism with no approximations, for the calculation of beam deflections. They have applied this technique to a number of bulk and thin film systems, from which representative results are presented. Author (revised)

Ellipsometric measurements are extremely sensitive (on the monolayer scale) to layer thicknesses and surface or interfacial roughness. However, lateral resolution is poor because of the need for a highly collimated (less than or equal to 0.05 degrees) and therefore large diameter (typically 1 mm) optical beam. Many materials are inhomogeneous on a smaller lateral scale, in which case conventional ellipsometry simply measures some average value. Focusing the beam leads, for an incoherent light source, to an uncollimated beam and a consequential spread in the angle of incidence, which in turn degrades the sensitivity. This paper describes a technique for focusing a coherent, Gaussian laser beam to a minimum spot size of about 30 micron x 130 micron, while maintaining a negligible effective spread in angle of incidence. The technique is used to measure semi-insulating (S.I.) GaAs, laser annealed ion implanted GaAs, and In(x)Ga(1-x)As strained layer structures. Author (revised)

Spectroscopic ellipsometry (SE) is employed to characterize Si/Si(1-x)Ge(x) strained-layer superlattices. An algorithm was developed, using the available optical constants measured at a number of fixed x values of Ge composition, to compute the dielectric function spectrum of Si(1-x)Ge(x) at an arbitrary x value in the spectral range 1.7 to 5.6 eV. The ellipsometrically determined superlattice thicknesses and alloy compositional fractions are in excellent agreement with results from high-resolution x ray diffraction studies. The silicon surfaces of the superlattices were subjected to a 9:1 HF cleaning prior to the SE measurements. The HF solution removed silicon oxides on the semiconductor surface and terminated the Si surface with hydrogen-silicon bonds, which were monitored over a period of several weeks, after the HF cleaning, by SE measurements. An equivalent dielectric layer model was established to describe the hydrogen-terminated Si surface layer. The passivated Si surface remained unchanged for greater than two hours, and very little surface oxidation took place even over three to four days. Author (revised)

FUNDAMENTALS AND APPLICATIONS OF VARIABLE ANGLE SPECTROSCOPIC ELLIPSOMETRY Abstract Only **c25**
John A. Woollam and Paul G. Snyder *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Materials Science and Engineering (Netherlands, Elsevier Sequoia), 1990 p 279-283 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

Being able to accurately select the angle of incidence and spectral range for measurement makes ellipsometry a very powerful tool for materials, surface, and interface analysis. The technique is fast, is totally computer automated, and can be performed at atmospheric pressure. It is totally non-invasive and is sensitive to fractions of atom layer thicknesses. The paper illustrates the power of variable angle spectroscopic ellipsometry with three examples: optical coatings, surface roughness and wetting, and electric field effects in semiconductor studies. Author (revised)

NON-DESTRUCTIVE EVALUATION IN MANUFACTURING USING SPECTROSCOPIC ELLIPSOMETRY Abstract Only **c38**
John A. Woollam and Paul G. Snyder *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from Review of Progress in Quantitative Nondestructive Evaluation (NY, Plenum Press), v. 10B, 1991 p 2185 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The manufacture of optical coatings, computer disks, as well as advanced electronic multilayered devices and circuit structures requires high precision in the measurement and control of thicknesses and interfacial and surface roughnesses. Variable angle spectroscopic ellipsometry (VASE) is non-destructive and monolayer sensitive. VASE uses polarized light, and the technique can be applied in nearly any ambient, including air, vacuum, or corrosive environment. Applications to coated window glass, space protective coatings, semiconductor device, as well as sputtered media computer disk manufacturing are discussed. At the present time these NDE measurements are mainly ex-situ, but in-situ (during deposition) applications are being rapidly developed. Derived from text

IN-SITU AND EX-SITU ELLIPSOMETRIC CHARACTERIZATION FOR SEMICONDUCTOR TECHNOLOGY Abstract Only
John A. Woollam, Paul G. Snyder, Huade D. Yao, and Blaine Johs (Woollam, John A. Co., Lincoln, NE.) *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Repr. from SPIE, v. 1678, 1992 p 246 Sponsored in part by DARPA (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The ellipsometric technique has been around since the end of the last century. However, until the introduction of computers in the 1960's, mainly nulling techniques were used. These were accurate, but extremely slow, and data analysis capabilities were limited. The use of personal computers permits rapid data acquisition and analysis. Thus the emphasis is now on ellipsometry for materials research and analysis. Ellipsometry is a unique tool in that it is totally non-destructive and can be performed in any ambient, including air, vacuum, high pressure, or liquid. In ellipsometry a polarized, collimated beam of monochromatic light is reflected at a preselected angle of incidence from the surface of a material, and the polarization state of the reflected beam is determined. For each wavelength and angle of incidence, one pair of numbers is obtained. These can be used to determine at most two materials parameters, such as the real and imaginary parts of the complex dielectric functions. Frequently, however, two or more variables are correlated and cannot be uniquely determined. This is an important caveat for ellipsometry: one always obtains numbers from the experiment, but they may not be correct. It is extremely important for the user to understand the basis of regression analysis and the possibility for correlated variables when using ellipsometry for any new materials system. To minimize this possibility, multiple angles of incidence and wavelength are used to maximize sensitivity and uniquely determine parameter values. In general, ellipsometry determines the real and imaginary part of the optical dielectric function or equivalently the index of refraction and extinction coefficient. For filmed materials systems, one can potentially determine film thickness (with monolayer sensitivity), void fraction (density), alloy fraction, interfacial and/or surface roughness, and other microstructural properties. To do these sophisticated levels of microstructural materials analysis requires spectroscopic and variable angle measurements, in order to minimize correlation, increase sensitivity, and maximize total information obtained. VASE (VARIABLE ANGLE SPECTROSCOPIC ELLIPSOMETRY) Abstract Only **c25**
John A. Woollam and Paul G. Snyder *In its* Materials, Structures, and Devices for High-Speed Electronics 1993 1 p Presented 6 Jan. 1992 (For primary document see N94-20971 05-76)
Avail: CASI HC A01/MF A01

The technique of ellipsometry was introduced in the 1800s, but until computers became available, it was painfully slow to perform. Rapid advances in small computer technology have made ellipsometric data acquisition rapid and accurate. Most important, fast personal computers make possible quick and convenient analysis of data from complex material structures. Early work in ellipsometry focused on improving the technique, whereas attention now emphasizes applications to materials analysis. New uses continue to be found; however, ellipsometry traditionally has been used to determine film thicknesses (in the range 1-1000 nm), as well as optical constants. Common systems are oxide and nitride films on silicon wafers, dielectric films deposited on optical surfaces, and multilayer semiconductor structures. In ellipsometry a collimated polarized light beam is directed at the material under study, and the polarization state of the reflected light is determined using a second polarizer. To maximize sensitivity and accuracy, the angle that the light makes to the sample normal (the angle of incidence) and the wavelength are controlled. Ellipsometry is a very powerful, simple, and totally nondestructive technique for determining optical constants, film thicknesses in multilayered systems, surface roughness, and other microstructural properties. THERMAL EXPANSION OF ELECTRONIC HIGHLY CORRELATED MATERIALS Ph.D. Thesis [THERMISCHE AUSDEHNUNG VON ELEKTRONISCH HOCHKORRELIERTEN MATERIALIEN]
Michael Lang 1991 148 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality (ETN-93-93605) Avail: CASI HC A07

Dilatometric examinations of electronically highly correlated materials were carried out, with special consideration of heavy fermion-superconductors CeCu2Si2 and of ceramic oxides of high temperature superconductors such as La(2-x)M(x)CuO4 and YBa2Cu3O(7-delta) to establish relationships between grid properties and superconduction in these systems. A capacitive measuring process was used, by which length variations of a specimen cause distance variations of electrodes in a plate condensator. A strongly anisotropic expansion behavior of CeCu2Si2 is noticed at superconducting phase transition. A thermodynamic analysis and specific heat measurements were carried out to show that the shortest Ce-Ce distance has an important influence on superconduction properties. A reduction of grid parameter is shown to increase the Kondo grid temperature. It is concluded that superconduction and magnetism in CeCu2Si2 appears to be narrowly linked. A grid anomaly is observed in systems La(2-x)Sr(x)CuO4, La(2-x)Ba(x)CuO4 and YBa2CuO7 which is assumed to lie in the CuO6 octahedron. ESA

OPTICAL AMPLIFICATION AND THRESHOLD BEHAVIOR ON InGaAs/InGaAsP MULTIQUANTUM WELL STRUCTURES Ph.D. Thesis [OPTISCHE VERSTAERKUNG UND SCHWELLVERHALTEN VON INGAAS/INGAASP-MULTI-QUANTUM-WELL-STUKTUREN]
Martin Moehrle 1992 144 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality (ETN-93-94181) Avail: CASI HC A07

A systematic analysis of optical amplification, losses, and threshold current properties of optically or electrically pumped InGaAs/InGaAsP quantum well laser structures is carried out. Broad area and ridge waveguide laser elements were built from these structures for examination by electrical excitation. A theoretical model was achieved for calculation of structure optical amplification with focus on optical amplification maximal value dependence of charge carried density, which is established to be correctly described by a logarithmic relationship. The influence of barrier width and an additional optical wave guide on this dependence was examined. Threshold current densities of structrures and charge carrier injection by electrical excitation were studied and optical amplification by electrical and optical excitation was compared. Influence of optical losses, injection efficiency, and charge carrier lifetime in InGaAs/InGaAsP quantum well structures was estimated. It is shown that multiquantum well structures have a threshold current minimum for a characteristical resonator length and low threshold currents can be obtained by high resonator lengths with InGaAsP bulk lasers with thin active layer. GROWTH, CHARACTERIZATION AND DEVICE DEVELOPMENT IN MONOCRYSTALLINE DIAMOND FILMS Quarterly Technical Report, 1 Jul. - 30 Sep. 1993
Robert F. Davis, Jeffrey T. Glass, and R. J. Nemanich Sep. 1993 35 p (Contract N00014-93-I-0437)
(AD-A272715) Avail: CASI HC A03/MF A01

For the heteroepitaxial deposition of diamond films, material selection criteria have been used to choose the closely lattice parameter matched substrate of Cu and the subsequent candidate interlayer materials of Ni, Si and Ti, the latter of which hold promise for both pseudomorphic matching to Cu and the promotion of the high density nucleation of diamond. Initial experiments of the Cu/Ti system have shown that a 20 A Ti layer can improve the particle density on Cu by nearly a factor of ten. Copper films have been evaporated under UHV conditions for examination as rectifying contacts. Atomic force microscopy indicated island growth of the Cu. Current-voltage measurements and UPS at 293 K revealed rectifying characteristics and a Phi approximately equal to 1.1 eV, respectively. In research regarding the negative electron affinity of the 2x1 diamond (100) surface, theoretical calculations indicate that it is associated with a monohydride terminated surface. DTIC

SCANNING TUNNELING MICROSCOPY INVESTIGATIONS OF METAL DICHALCOGENIDE MATERIALS Final Report, 1 Nov. 1989 - 30 Jun. 1993
Charles M. Lieber 25 Oct. 1993 44 p
(Grant AF-AFOSR-0029-90)
(AD-A272910; AFOSR-93-0841TR) Avail: CASI HC A03/MF A01

Scanning tunneling microscopy (STM) and atomic force microscopy (AFM) were used to characterize the atomic level structure of electronic properties, reactivity, and wear of metal dichalcogenide materials that are or have potential as solid state lubricants. Single crystals of MoS2, Ni(x)Mo(1-x)S2, MoS(2-x)Se(x), and MoS(2-x)Te(x) were prepared to determine how chemical modifications affect the local structure and electronic properties of this lubricant. STM images of Ni-doped MoS2 show localized electronic states due to the Ni atoms, while images of Se- and Te-doped materials indicate that anion substitution is electronically delocalized. AFM studies of Te-doped MoS2 show, however, that the tellurium dopants form atomic scale structural protrusions that may reduce sliding friction. AFM was also used to characterize nanometer scale wear and oxidation on MoS2 and NbSe2 surfaces. In atmosphere at room-temperature AFM studies showed that NbSe2 wears approximately three times faster than MoS2. Furthermore, oxidation studies demonstrated that NbSe2 was significantly more reactive than MoS2 with molecular oxygen. These results indicate that the intrinsic stability of the MoS2 surface make it an effective lubricant, AFM was also used to elucidate the growth of MoO3 on the surface Of MoS2 during oxidation, and to study wear properties of these MoO3 crystallites. The AFM tip was used to define lines with 10 nm resolution in MoO3 and to manipulate distinct MoO3 structures on the MoS2 surface. In addition, metal-substitution in TaS2 was studied systematically using STM and theoretical methods. DTIC

SOLID-STATE DYNAMICS AND QUANTUM TRANSPORT IN NOVEL SEMICONDUCTOR NANOSTRUCTURES Annual Report, 1 Oct. 1992 - 30 Sep. 1993
K. W. Kim 30 Sep. 1993 51 p
(Contract N00014-90-J-1835)
(AD-A272955) Avail: CASI HC A04/MF A01

The objective of this research program is to study theoretically the underlying principles of solid-state dynamics and quantum mechanical transport of carriers in ultra-small novel semiconductor devices. The areas of research are: theory of phonon modes in reduced dimensions, effects of band structure on electronic and optical properties of heterostructures, and quantum transport in solids with special emphasis on non-perturbative role of high-electric fields and many-body effects in dynamical processes. The treatment of these problems is mainly analytical through the development of macroscopic and microscopic physical models with an emphasis on quantum mechanical principles. At the same time, numerical approaches has also been utilized for realistic solutions with accuracy. Specific subjects discussed in this report include the effects of confinement and localization on optical phonon modes, band mixing in tunneling, Bloch electron quantum transport theory under hot-electron conditions, and dielectric response function theory. (DE93-017620; EGG-10617-2184; CONF-9303206-1) Avail: CASI HC A02/MF A01

X-ray topography and rocking curve experiments were performed on (alpha)-mercuric iodide samples. As-grown crystals were examined for intrinsic defects and crystallinity. Orientation of certain defects depends on the direction of crystal growth. The propagation of as-grown crystalline features was documented. The extent of crystal damage introduced during various steps of device fabrication such as sawing, polishing, etching and contact deposition was explored. Coefficients of linear thermal expansion of alpha(sub 33) = 54 +/- 5 x 10(exp -6)/C along the tetragonal c-axis, (001) direction and alpha(sub 11) = 11 +/- 4 x 10(exp -6)/C in the (100) direction were measured. INVESTIGATION OF THE EFFECT OF VARIOUS OXIDE AND FLUORIDE ADDITIVES ON THE MICROSTRUCTURE, ELECTRONIC PROPERTIES, AND PHASE SHIFTING ABILITY OF Ba(1-x)Sr(x)TiO3 Final Report
L. C. Sengupta, E. Ngo, S. Stowell, R. Lancto, and W. C. Drach Sep. 1993 27 p
(AD-A271756; ARL-TR-217) Avail: CASI HC A03/MF A01

A ceramic phase shifting device (used in phased array antenna systems) has been demonstrated using Ba(1-x)Sr(x)TiO3 (BSTO) ceramics. As a part of an effort to optimize the electronic device performance in the phase shifter, various dopants have been incorporated into BSTO. The effects of these additives on the Curie temperature, dielectric properties, tunability, hysteresis, and grain size have been investigated. The homogeneity of the doped materials has been verified using Curie-Weiss analysis. To further improve the electrical performance, some higher levels of doping have been attempted. A few of the latest results for these ceramic-ceramic composites will be presented. DTIC

INFRARED ABSORPTION SPECTROSCOPY OF THE WEAKLY BONDED CO-Cl2 COMPLEX Final Report, Aug. 1990 - Aug. 1991
Steven W. Bunte, Jason B. Miller (Denison Univ., Granville, OH.), Zhi-Song S. Huang (Florida Univ., Gainesville.), Juan E. Verdasco (Universidad Complutense, Madrid, Spain.), Curt Wittig (California Univ., Los Angeles.), and Robert A. Beaudet (California Univ., Los Angeles.) Sep. 1993 23 p
(Contract DE-FG03-89ER-04053; DA Proj. 1L1-61192-SAH-43)
(AD-A271757; ARL-TR-202) Avail: CASI HC A03/MF A01

High-resolution rovibrational absorption spectra of the weakly bonded CO-Cl2 complex have been recorded in the 2143/cm region by exciting the CO chromophore with a tunable diode laser. The spectra indicate that CO-Cl2 is linear and semirigid. The distance between the CO and Cl2 centers of mass is approximately 4.78 A. The orientation of CO is not determined experimentally. However, Cl2 appears to act as a classical sigma electron acceptor, while CO behaves like a weak Lewis base donating charge from the carbon side via the weakly antibonding sigma orbital, thereby raising the CO vibrational frequency. This quarter the first production of continuous diamond films in our 75kW reactor were seen. Our efforts concentrated on three fronts: improving reliability and capability of the reactor, understanding the diamond growth chemistry and how it compares to the prototype operation, and further modeling for refining the reactor design. On the first front, the reactor is regularly operated around the clock, and the power utilized in diamond growth as well as the design and thermal control of the substrate stage is steadily improved. On the second front, a series of deposition runs using a matrix of conditions to investigate the effects of gas composition and throughput on growth rate and diamond quality were initiated. These runs included real time pyrometry, emission spectroscopy, and residual gas analysis for comparison with prototype operation and modeling. Our first iteration yielded what we believe is a world record of over 350 mg/hr of CVD diamond at only 40 kW of microwave power. Our near term goals include: (1) production of free-standing 6 diameter films, (2) finishing the current iteration of chemistry matrix runs and understanding the similarities (and differences) with our 2.45 GHz prototype; and (3) further increasing power delivered to the plasma, and power removal capability of the substrate stage. DEPHASING PROCESSES IN III-V SEMICONDUCTORS Report, 1 Oct. 1992 - 30 Sep. 1993
Guy D. Gilliland Sep. 1993 153 p
(Contract N00014-92-J-1927)
(AD-A271677) Avail: CASI HC A08/MF A02

Our study has dealt with both experimental and theoretical studies of electronic 'dephasing' processes in a variety of model semiconductor systems, all based upon III-V materials and heterostructures. Attention has been primarily given to dephasing processes in excitonic systems, however, free-carrier dynamics have not been ignored. We have studied the following model systems: exciton-polaritons in GaAs, 3D bulk excitons in GaAs, quasi-2D interface excitons in GaAs/Al(x)Ga(1-x)As heterostructures, excitons and free-carriers in ordered In(x)Ga(1-x)P. Experimental techniques utilized include: photoluminescence (PL), PL-excitation, PL decay kinetics, time-resolved PL-excitation, resonant Raman scattering, time-resolved spectroscopics, resonant Brillouin scattering, and all optical carrier transport measurements. DTIC

(Contract N00014-90-J-1604)
(AD-A273097) Avail: CASI HC A08/MF A02

The effects of hydrogen on cluster binding energy and resulting growth mode during chemical vapor deposition of diamond, the process parameters and the effect of substrates during bias enhanced nucleation, the growth of textured diamond films, and the characterization of these films using transmission electron microscopy, Raman spectroscopy, and photo-luminescence comprise the growth and thin film characterization research conducted during this grant. Additional work included determination of the surface properties including the negative electron affinity, the growth and characterization of SiGe contacts, and the modeling and characterization of electronic devices. The nucleation of diamond grains on unscratched Si(100) wafer is enhanced by four orders of magnitude relative to scratched substrates by using negative bias-enhanced microwave plasma CVD in a 2% methane/hydrogen plasma for an initial period. In vacuo surface analysis has revealed that the actual nucleation occurs on the amorphous C coating present on the thin SiC layer which forms as the product of the initial reaction with the Si surface. It is believed that the C forms critical clusters which are favorable for diamond nucleation. TEM of nucleation of diamonds on single crystal SiC showed that approximately half of the diamond nuclei were in epitaxial alignment with the SiC substrate. UV photoemission spectroscopy has revealed Schottky barrier heights of 1.0 +/- 0.2 eV and 1.5 +/- 0.2 for the Ti-diamond (111) and (100) interfaces. DTIC

SYNTHESIS AND CATALYTIC PROPERTIES OF METAL AND SEMICONDUCTOR NANOCLUSTERS
J. P. Wilcoxon, T. Martino, E. Klavetter, and A. P. Sylwester 1993 9 p Presented at the North Atlantic Treaty Organization (NATO) Advanced Study Meeting of Institute on Nanophas Materials, Corfu, Greece, 20 Jun. - 2 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019418; SAND-93-1846C; CONF-9306223-1) Avail: CASI HC A02/MF A01

Synthesis of metal or semiconductor nanoclusters in microheterogeneous oil-continuous inverse micelle systems is discussed. We focus on synthesis and catalytic properties of palladium, iron, and iron sulfide nanoclusters. Cluster size-control is achieved by changing the micelle size which is determined by small angle neutron scattering (SANS) and chosen to produce cluster in size range of 1-20 nm. Cluster sizes were determined by either transmission electron microscopy (TEM) or small-angle x-ray scattering (SAXS). Cluster structure was determined by either x-ray or electron diffraction. In the case of Fe nanoclusters, the crystal structure depended

on the chemical nature of the surfactant micelle used in the synthesis, illustrating the important role of the surfactant during the growth process. Results of in-situ pyrene hydrogenation using size-selected Pd clusters show a significant increase in activity/total surface area as the size decreases. These clusters also proved effective as unsupported catalysts for direct coal hydropyrolysis, even at very low metal concentrations. Synthesis and optical features of a new semiconductor cluster material, FeS2, are discussed with regard to its use in photocatalysis. Application of FeS2 in coal hydrogenolysis reactions has improved yields of short chain hydrocarbons significantly compared to conventional FeS2 powders. DOE

DEFECT MOTION AS THE ORIGIN OF THE 1/f CONDUCTANCE NOISE IN SOLIDS

V. B. Orlov (Gorky N. I. Lobachevsky State Univ., USSR.) Jun. 1992 75 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(EUT-92-E-259; ISBN-9-06-144259-1; ETN-94-94766) Avail: CASI HC A04

The nature of 1/f conductance fluctuations in solids is considered in models attributing this phenomenon to some kind of defect motion. Stochastic changes in the state of the system 'lattice defects' are treated as a noise source affecting the number and/or the mobility of charge carriers and providing the 1/f noise observed. In particular, the known model of Two Level Systems (TLS) and a more general approach of freely wandering defects within a randomized potential profile are discussed. Numerical estimations show that this noise model, previously established for metals, is relevant for semiconductors. The most basic properties of the 1/f conductance fluctuations in solids are described in this way: the bulk nature, the short range of spatial correlation, the detailed shape of the spectrum, and the thermoactivation. Experimental data are interpreted: correlation between the 1/f noise magnitude and the degree of crystal perfection, temperature dependence and field dependence in semiconductors, and 1/f noise in magnetoresistance. The possibility of characterization of defects by the noise spectroscopy is considered. ESA

FUNDAMENTAL STUDIES OF DEFECT GENERATION IN AMORPHOUS SILICON ALLOYS GROWN BY REMOTE PLASMA-ENHANCED CHEMICAL-VAPOR DEPOSITION

G. Lucovsky Aug. 1993 55 p Prepared for Midwest Research Inst., Golden, CO

(Contract DE-AC02-83CH-10093)

(DE93-017083; NREL/TP-451-5452) Avail: CASI HC A04/MF A01

This report describes research to reduce the intrinsic bonding defects in amorphous and microcrystalline Si alloys by controlling the bonding chemistry and the microstructure via the deposition process reactions. The specific approach was to use remote plasma-enhanced, chemical-vapor deposition (PECVD) and reactive magnetron sputtering to limit the multiplicity of deposition inaction pathways, and thereby gain increased control over the thin-film chemistry and microstructure. The research included the deposition of amorphous and microcrystalline Si alloy materials by the PECVD process and by reactive magnetron sputtering and the evaluation of the material properties of these films for potential applications in PV devices. The focus of the research was on gaining a fundamental understanding of the relationships between deposition reaction pathways, the bonding of dopant and alloy atoms, and the electrical properties of importance for PV applications. This involved studying the factors that contribute to defect generation and to defect removal and/or neutralization. In addition to the experimental studies, the research also included theoretical and modeling studies aimed at understanding the relationships between local atomic arrangements of Si and alloy atoms, and the electrical, optical, vibrational, and defect properties. RESEARCH ON POLYCRYSTALLINE THIN-FILM SUBMODULES BASED ON CuInSe2 MATERIALS

R. Arya, J. Fogleboch, T. Lommasson, R. Podlesny, L. Russell, S. Skibo, S. Wiedeman, A. Rothwarf, and R. Birkmire Sep. 1993 64 p Prepared for Midwest Research Inst., Golden, CO

(Contract DE-AC02-83CH-10093)

(DE93-018223; NREL/TP-413-5759) Avail: CASI HC A04/MF A01

This report describes a 3-year, cost-shared research program at Solarex to develop all pertinent processes and technologies required to achieve the goal of 12% CIS submodule (with areas greater than 900 sq cm). The work is focused on four tasks: window layers, contacts, and substrate; CIS absorber layer; device structure; and submodule design and encapsulation. Each task addresses basic material improvements, fabrication and characterization of CIS solar cells, and scale up of processes to large-area substrates. DOE

RELAXATION OF HYSTERESIS LOOP IN A SINGLE CRYSTAL OF YBa2Cu4O8

Ming Xu (Ames Lab., IA.), D. K. Finnemore (Ames Lab., IA.), G. W. Crabtree, V. M. Vinokur, D. G. Hinks, K. Zhang (Chicago Univ., IL.), and B. Dabrowski Apr. 1993 3 p Presented at the Conference of the International Union of Pure and Applied Physics on Low Temperature Physics (LT 20), Eugene, OR, 1-11 Aug. 1993

(Contract W-31-109-eng-38)

(DE93-019519; ANL/MSD/CP-79655; CONF-930801-9) Avail: CASI HC A01/MF A01

Magnetic relaxation has been studied for YBa2Cu4O8 in order to look for changes in the relaxation rates that arise because different pinning mechanisms dominate in different magnetic field regimes. In the low field regime where the Bean-Livingston surface barrier dominates, the vortices exit on a field decreasing branch with a relaxation rate about ten times faster than they enter on a corresponding field increasing branch. In high magnetic fields where bulk pinning dominates, the relaxation rates for field increasing and field decreasing are essentially the same. DOE

(DE93-041101; SAND-93-1430) Avail: CASI HC A05/MF A02

The Milling Assistant (MA) programming system demonstrates the automated development of tool paths for Numerical Control (NC) machine tools. By integrating a Case-Based Reasoning decision processor with a commercial CAD/CAM software, intelligent tool path files for milled and point-to-point features can be created. The operational system is capable of reducing the time required to program a variety of parts and improving product quality by collecting and utilizing 'best of practice' machining strategies. DOE

APPLICATION OF AN ELECTROCHEMICAL QUARTZ CRYSTAL MICROBALANCE TO THE STUDY OF ELECTROCATALYTIC FILMS Ph.D. Thesis

J. S. Gordon, Jr. 1 Sep. 1993 223 p Limited Reproducibility: More

than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-82)
(DE93-041124; IS-T-1670) Avail: CASI HC A10

The Electrochemical Quartz Crystal Microbalance (EQCM) was used to study the deposition and composition of electrodeposited pure PbO2 and Bi-doped PbO2 active toward anodic oxygen-transfer reactions. Within the doped films, Bi is incorporated as Bi(sup +5) in the form of BiO2A, where A is ClO4(-) or NO3(-). For deposition of these 2 materials, changes in hydration between the Au oxide and the depositing film resulted in higher mass-to-charge ratios. XRD and XPS were used to study the films; the rutile structure of PbO2 is retained even with the Bi doping. The EQCM was also used to study the formation and dissolution of Au oxide and preoxide structures formed on the Au substrate electrodes in acidic media. The preoxide structures were AuOH and increased the surface mass. For the formation of stable Au films on quartz wafers, Ti interlayers between Au and quartz was found to be very effective. DOE

The effects of co-implantation on the electrical activity of C acceptors have been studied using a series of elements as co-implants. A variety of electrical and structural techniques were used for characterization. It is found that although co-implantation with heavy ions improves the substitutionality of C atoms on As sites, a high electrical activity of the C(sub As) acceptors is attained only if the stoichiometry is maintained through co-implantation of group 3 atoms. LOCAL STRUCTURE IN OXYGEN-DOPED La2CuO(4+DELTA)
P. C. Hammel, A. P. Reyes, E. T. Ahrens, D. E. MacLaughlin, J. D. Thompson, Z. Fisk, P. C. Canfield, S. W. Cheong, and J. E. Schirber (Sandia National Labs., Albuquerque, NM.) Aug. 1993 11 p Presented at the International Conference on Strongly Correlated Electron Systems, La Jolla, CA, 16-19 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE93-040248; LA-UR-93-2879; CONF-930865-7) Avail: CASI HC A03

Oxygen doped La2CuO(4+delta), due to the unusually large mobility of the oxygen ions at high temperatures, is the only cuprate which has macroscopic phase separation of doped holes. We discuss our studies of La2CuO(4+delta), including phase separation, distributed local structure whose onset coincides with-phase separation and the observation that in the presence of doped holes two distinct copper sites are generated, an observation which contrasts with results of diffraction studies. The superconducting transition temperature Tc in this material changes by over 10% in response to altered cooling history. Below a temperature T(sub f), the situation becomes similar to other cuprates since oxygen is no longer sufficiently mobile to allow further macroscopic phase separation. In this regime, the magnetic behavior of metallic La2CuO(4+delta) is conventional in context of cuprates. However La-139 NMR spectroscopy has shown the local structure of the La-O layer to be very sensitive to the presence of doped holes and to be strongly temperature dependent in this same regime. This sensitivity is evident in the CuO2 planes where, in the presence of doped holes a second, distinct copper site is present. This provides an opportunity to explore the relationship between local structure and the novel magnetic behavior of the cuprates. DOE

CHARACTERIZATION OF CONVECTION RELATED DEFECTS IN II-VI COMPOUND SEMICONDUCTORS Final Report, 22 May - 30 Sep. 1992
August F. Witt Dec. 1993 13 p
(Grant NAG8-913)
(NASA-CR-194704; NAS 1.26:194704) Avail: CASI HC A03/MF A01

The research carried out under NAG8-913, 'Characterization of Convection Related Defects in II-VI Compound Semiconductors', was aimed at exploration of the potential of axial magnetic fields for melt stabilization when applied in Bridgman geometry to the growth of HgMnTe. The thrust of the work was directed at the experimental establishment of the limits of magnetic melt stabilization during crystal growth and at the analytical verification of the effects of stabilization on critical materials properties. The data obtained indicate noticeable stabilization effects, particularly as far as the formation of microscopic compositional inhomogeneities is concerned. The effects of magnetic fields on precipitate formation are found to be minor. Magnetic field effects were investigated for both 'Bridgman' and 'travelling heater' geometries. The research was conducted during the period from May 22 to September 30, 1992. Author (revised)

THE n-p(p(+))-n Al(yGa)(1-y) As-GaAs-In(x)Ga(1-x) AS QUANTUM WELL LASER WITH p(+)-n(+)GaAs-InGaAs TUNNEL CONTACT ON n GaAs
A. R. Sugg, E. I. Chen, T. A. Richard, S. A. Maranowski, and N. Holonyak, Jr. 17 May 1993 4 p Repr. from Applied Physics Letters, v. 62, no. 20, 17 May 1993 p 2510-2512 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-92-G-0264)
(AD-A271292; ARO-30090.3-EL) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Data are presented on the growth, by metalorganic chemical vapor deposition, and fabrication of n-p (n-up) AlGaAs-GaAs-InGaAs quantum-well heterostructure lasers using a p(+)-n(+) GaAs-InGaAs reverse-biased tunnel junction to contact the n-type GaAs substrate. The lasers operate continuously at 300 K with a threshold of approximately 37 mA for a 10-micrometer-wide native-oxide-defined gain-guided stripe (cavity length approximately 375 micrometers). Comparison tunnel junctions similar to those used in the diode lasers are also fabricated and exhibit low reverse-biased series resistances (approximately 2.2 ohms, area approximately 4.5 times larger). DTIC

SPIN-POLARON THEORY OF HIGH-T(c) SUPERCONDUCTIVITY. 3: GAP FUNCTION AND CRITICAL TEMPERATURE
R. F. Wood Jun. 1993 18 p Presented at the International Symposium

on High-Tc Superconductivity and Its Applications, Cairo, Egypt, 4-16 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-019198; CONF-9304191-2) Avail: CASI HC A03/MF A01

Results from previous papers in this series are used to derive approximate expressions for the gap and T(sub c) within the framework of a Cooper-pairing approach. The possible symmetry types of the gap are discussed. It is shown how the proximity of the Fermi level to the Mott-Hubbard band edge and the interplay of O 2p-sigma and 2p-pi bands and/or localization effects can provide good fits to the variation of T(sub c) with x in La(2-x)Sr(x)CuO4 and YBa2Cu3O(7-x). It is concluded that the in-plane gap is either s- or d-like but anisotropic in either case. Other aspects and implications of the model and of the calculations are given and comparisons with Mott's spin-bipolaron model are made. DOE

ENERGY-RESOLVING X RAY DETECTORS WITH CHARGE AMPLIFICATION DUE TO MULTIPLE QUASIPARTICLE TUNNELING
C. A. Mears, S. E. Labov, and A. T. Barfknecht (Conductus, Inc., Sunnyvale, CA.) 1993 4 p Presented at the International Superconductive Electronic Conference, Boulder, CO, 11-14 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts W-7405-eng-48; DE-FG02-91ER-81190)
(DE93-019506; UCRL-JC-114285; CONF-930863-1) Avail: CASI HC A01

A single 6 keV x ray absorbed in a superconductor produces more than a million electrons in excited states, called quasiparticles. The number of quasiparticles is proportional to the energy of the incident x ray and can be determined by measuring the increase in tunneling current through a thin oxide barrier between two superconducting layers. The energy resolution of an x ray detector based on such a measurement in principle could be limited only by the statistical variation in the number of quasiparticles produced. If this is the case, the resolution for 6 keV x rays absorbed in niobium (Delta = 1.5 meV) should be better than 5 eV. While high resolution has been achieved with superconducting tunnel junction detectors, the best resolution obtained is about ten times worse than this limit. The energy resolution of previous work was often limited by electronic noise produced in the charge amplification system. In order to minimize the effects of electronic noise, we developed a detector using a new geometry where each quasiparticle produced is trapped near the tunnel barrier and tunnels several times before it recombines into a Cooper pair, thus increasing the charge measured for a given x-ray. Because of this larger charge, the contribution of electronic noise to the energy resolution of the detector is minimized. DOE

FULLERENE DERIVATIVES AND FULLERENE SUPERCONDUCTORS
H. H. Wang, J. A. Schlueter, and A. C. Cooper 1993 36 p Presented at the US/Japan Seminar on Physics and Chemistry of C(sub 60) and Related Compounds, Honolulu, HI, 10-23 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-019568; ANL/CHM/CP-80106; CONF-9307123-1) Avail: CASI HC A03/MF A01

A series of 1:1 C60 cycloaddition adducts, C60A (A = anthracene, butadiene, cyclopentadiene, and methyl cyclopentadiene), has been synthesized. The products are cleanly separated and characterized by use of TGA, H-1 NMR, IR, and mass spectrometry. Among these adducts, C60(methyl cyclopentadiene) showed the highest thermal stability and was doped with three equivalents of rubidium. The resulting Rb3C60(MeCp) is a semiconductor but can be thermally converted to the superconducting Rb3C60 through a retro-Diels-Alder reaction. A one-step doping process to prepare Rb3C60 crystals has been developed. The optimal doping condition occurs at approximately 300 degrees C. High superconducting shielding fractions between 60 and 90% and sharp transition widths (Delta-T(sub 10-90) between 4 and 0.7 K) were measured for these samples. DOE

HYDROGEN IN COMPOUND SEMICONDUCTORS
E. E. Haller May 1993 10 p Presented at the 12th Record of Alloy Semiconductor Physics and Electronics Symposium, Izunagaoka, Japan, 14-16 Jul. 1993
(Contract DE-AC03-76SF-00098)
(DE93-040300; LBL-34395; CONF-9307139-1) Avail: CASI HC A02/MF A01

Progress in the understanding of hydrogen and its interactions in III/V and II/VI compound semiconductors is reviewed. Donor, acceptor, and deep level passivation is well established in III/V compounds based on electrical measurements and on spectroscopic studies. The hydrogen donor levels in GaAs and GaP are estimated to lie near E(sub v)+0.5 eV and E(sub v)+0.3 eV, respectively. Arsenic acceptors have been passivated by hydrogen in CdTe and the very first nitrogen-hydrogen local vibrational model spectra in ZnSe have been reported. This long awaited result may lead to an explanation for the poor activation of nitrogen acceptors in ZnSe grown by techniques which involve high concentrations of hydrogen. DOE

SPECIFIC HEAT OF YBa2Cu3O7
N. E. Phillips, J. P. Emerson, R. A. Fisher, B. F. Woodfield, D. A. Wright, and J. E. Gordon Aug. 1993 18 p Presented at the Physics and Chemistry of Molecular and Oxide Superconductors, Eugene, OR, 27-31 Jul. 1993
(Contract DE-AC03-76SF-00098)
(DE93-040640; LBL-34523; CONF-930710-2) Avail: CASI HC A03/MF A01

Specific heat measurements, including measurements in magnetic fields and at both low temperatures and near T(sub c), on a number of YBa2Cu3O7 samples have revealed several correlations among strongly sample dependent parameters. These correlations suggest that the sample dependence of the parameters reflects a sample dependence of the volume fraction of superconductivity, which is in turn correlated with a low concentration of Cu(2+) moments. The correlations give a criterion for recognizing the value of the parameters characteristic of the fully superconducting material. Preliminary results on effects of sample heat treatment are reported. New data on the 'linear term' is presented and discussed. DOE

(DE93-040822; ANL/MSD/CP-80646; CONF-9308175-1) Avail: CASI HC A03/MF A01

We have grown via sputtering, Fe - iron silicide superlattices that exhibit novel thermal and photomagnetic effects. For approximately 15 A nominal thickness of the silicide layer the superlattices are antiferromagnetically (AF) coupled at room temperature. Upon cooling below 100K, they gradually revert to ferromagnetic alignment, but the AF coupling is restored at low temperature by exposure to visible light off sufficient intensity (greater than 10 mW/mm(exp 2)). These effects are due to charge carriers in the silicide spacer layer which, when thermally or photo-generated, are capable of communicating spin information between the Fe layers. DOE

THE INCONGRUENT MELTING AND MELT TEXTURED SOLIDIFICATION PROCESS OF Bi2Sr2CaCu3O8 Ph.D. Thesis
J. Polonka 1993 118 p
(Contract W-7405-eng-82)
(DE93-041123; IS-T-1665) Avail: CASI HC A06/MF A02

The melting and solidification was studied using in-situ high temperature XRD from melting point to 900 C in 0.2, 0.1, 0.02 atm O2 and pure N2. The incongruent melting point of Bi2Sr2CaCu2O8 was lowered by decreasing the partial O2 pressure from 870 C (in .2 atm O2) to 830 C (in pure N2 atmosphere). As temperature was increased the incongruent melting of Bi2Sr2CaCu2O6 followed a phase sequence in which (Ca, Sr)CuO2 yields (Ca, Sr)CuO2 yields (Ca,Sr)O occur in presence of Bi-rich liquid. At 900 C, the only crystalline phase present in the melt was (Ca,Sr)O. This phase sequence remained the same for all four different partial O2 pressures. During the solidification of Bi2Sr2CaCuO8, from 10 C below the melting point to 760 C, the major phases that form depend on the partial O2 pressure. As partial O2 pressures was lowered from 0.2 to 0 atm, the major second phase formation out of the melt follows the sequence of (Ca, Sr)CuO2 yields (Ca,Sr)CuO2 Sr)CuO2 yields (Ca,Sr)O, respectively. At 0.1 atm partial O2 pressure and below, Bi2Sr2CaCu2O6 solidified out of the melt; at 0.2 atm of O2 Bi2Sr2CaCu2O6 forms instead. DOE

SIMPLE METHOD TO ESTIMATE MOS OXIDE-TRAP, INTERFACE-TRAP, AND BORDER-TRAP DENSITIES
D. M. Fleetwood, M. R. Shaneyfelt, and J. R. Schwank 1993 4 p Presented at the IEEE Semiconductor Interface Specialists Conference, Ft. Lauderdale, FL, 9-11 Dec. 1993
(Contract DE-AC04-76DP-00789)
(DE93-041138; SAND-93-1927C; CONF-931226-1) Avail: CASI HC A01/MF A01

Recent work has shown that near-interfacial oxide traps that communicates with the underlaying Si ('border traps') can play a significant role in determining MOS radiation response and long-term reliability. Thermally-stimulated-current 1/f noise, and frequency-dependent charge-pumping measurements have been used to estimate border-trap densities in MOS structures. These methods all require high-precision, low-noise measurements that are often difficult to perform and interpret. In this summary, we describe a new dual-transistor method to separate bulk-oxide-trap, interface-trap, and border-trap densities in irradiated MOS transistors that requires only standard threshold-voltage and high-frequency charge-pumping measurements. FABRICATION OF AMORPHOUS DIAMOND FILMS
S. Falabella, D. B. Boercker, and D. M. Sanders Apr. 1993 12 p Presented at the International Conference on Metallurgical Coatings and Thin Films, San Diego, CA, 19-23 Apr. 1993
(Contract W-7405-eng-48)
(DE94-000404; UCRL-JC-111960; CONF-930419-5) Avail: CASI HC A03/MF A01

Amorphous diamond (a:D) is a hard, electrically insulating, inert, and transparent form of carbon that has the sp3 bond character of crystalline diamond, but lacks a long-range ordered structure. Using our filtered cathodic arc system, we have produced a:D films at room temperature that demonstrate hardness above 8000 H(sub v), hydrogen content below 0.1%, density of 2.7 (plus or minus) 0.3 g/cc, and adhesion on tungsten carbide and silicon substrates above 10 kpsi. The fine structure of a:D was characterized by TEM and electron diffraction. TEM showed no evidence of any ordered structure down to 1 run. Unlike natural diamond or DLC, a:D has a flat transmission spectrum from 0.8 to over 50 which is due to its amorphous nature and the lack of hydrogen. Also, we determined the index of refraction of our a:D to be 2.47-2.57. The thermal diffusivity of a:D has been measured and reported for the first time. We have lowered the intrinsic stress in the films by the use of bias and the inclusion of impurity atoms, and produced films up to 8 gm thick on carbide tool bits. In addition, a molecular dynamics code has been used to model this material. DOE

We review the spin dynamics of the normal state of the cuprates with special emphasis on neutron data in both the YBa2Cu3O(7-delta) and La(2-x)Sr(x)CuO4 systems. When realistic models of the Fermi surface shapes are incorporated, along with a moderate degree of spin fluctuations, we find good semi-quantiative agreement with experiment for both cuprates. Building on the success of this Fermi-liquid-based scheme, we explore the implications for d-wave pairing from a number of vantage points. We conclude that our present experimental and theoretical understanding is inadequate to confirm or refute the d-wave scenario. DOE

Gupta (Centre National de la Recherche Scientifique, Meudon-Bellevue, France.), P. C. Canfield (Ames Lab., IA.), A. Migliori, and H. A. Borges 1993 14 p Presented at the International Conference on Strongly Correlated Electron Systems, La Jolla, CA, 16-19 Aug. 1993
(Contract W-7405-eng-36)
(DE93-040061; LA-UR-93-2919; CONF-930865-2) Avail: CASI HC A03/MF A01

We have studied magnetism in CeRu2Ge2 and CeRh2Ge2 through specific heat in zero and applied magnetic fields, dc magnetization, thermal expansion and electrical resistance measurements at pressures to 21 kbar. Both compounds have two transitions; although we argue that the higher one in CeRu2Ge2 is due to residual stress in the polycrystalline sample. The overall systematics are consistent with those found at ambient pressure in pseudoternaries formed with Si substitution for Ge. DOE

TEMPERATURE DEPENDENCE OF MAGNETIC ORDER IN SINGLE-CRYSTALLINE UPdSn
R. A. Robinson, A. C. Lawson, J. W. Lynn, and H. Nakotte (Amsterdam Univ., Netherlands.) 1993 17 p Presented at the 38th Annual Conference on Magnetism and Magnetic Materials, Minneapolis, MN, 15-18 Nov. 1993
(Contract W-7405-eng-36)
(DE93-040153; LA-UR-93-3155; CONF-931133-1) Avail: CASI HC A03/MF A01

The noncollinear hexagonal antiferromagnet UPdSn exhibits two magnetic phase transitions, at 35.5 K and 23 K. The first transition is from a hexagonal paramagnetic state to a noncollinear antiferromagnetic state with a doubled unit cell (phase one). The second 23-K transition is to a monoclinic magnetic structure (phase two). Ever since these transitions were discovered, the question has been whether the moments simply rotate at 23 K, or whether the y- and z-components of the moment order at 35.5 K while the x-component orders out of incipient fluctuations at the lower 23-K transition. While previous powder studies were rather inconclusive on this point, we now present new single-crystal neutron diffraction results that show the second picture to be correct. In addition we discuss the structural distortions that accompany the change in symmetry and show that there is phase two type magnetic short range order between 23 K and 35.5 K. DOE

SYNTHESIS AND CHARACTERIZATION OF CHARGE-SUBSTITUTED GARNETS YCaLnGa5O12 (Ln = Ce, Pr, Tb)
S. A. Gramsch and L. R. Morss 1993 15 p Presented at the 20th Rare Earth Research Conference, Monterey, CA, 12-17 Sep. 1993
(Contract W-31-109-eng-38)
(DE93-040227; ANL/CHM/CP-79242; CONF-9309142-4) Avail: CASI HC A03/MF A01

A low temperature method is described for the preparation of the new garnet compounds YCaLnGa5O12 (Ln=Ce, Pr, Tb). In this set of compounds Ca(2+) + Ln(4+) replaces 2 Y(3+) in the parent gallium based garnet Y3Ga5O12 in order to stabilize as effectively as possible the Ln(4+) species in the eight-coordinate 'A' site of the garnet structure. Characterization of the oxides by x-ray powder diffraction and thermogravimetric analysis is discussed with regard to the structural relationship of the substituted compound to the parent material. The tetravalent ions Pr(4+) and Tb(4+) exhibit increased thermal stability in reducing conditions as compared to the Ln(4+) states in the fluorite LnO2 and perovskite BaLnO3 type structures. This result is discussed with reference to the complex crystal chemistry of these systems. DOE

CRYSTAL STRUCTURE AND SHORT-RANGE OXYGEN DEFECTS IN La- AND Nd-MODIFIED ZrO2
C. K. Loong, J. W. Richardson, Jr., M. Ozawa (Nagoya Inst. of Tech., Japan.), and M. Kimura (Toyota Central Research and Development Labs., Inc., Aichi, Japan.) 1993 11 p Presented at the 20th Rare Earth Research Conference, Monterey, CA, 12-17 Sep. 1993
(Contract W-31-109-eng-38)
(DE93-040229; ANL/IPNS/CP-79265; CONF-9309142-3) Avail: CASI HC A03/MF A01

The crystal structure of rare-earth modified zirconia and the associated oxygen defects were studied by neutron diffraction. A Rietveld analysis of the neutron powder patterns of heat treated samples of La- and Nd-10mol%-ZrO2 revealed the composition of a major tetragonal phase (space group P4(sub 2)/nmc) and a minor cubic phase (space group Fm3m). The short-range oxygen defects structure was examined by a Fourier-filtering technique. A real-space correlation function, obtained from a Fourier transform of the filtered residual diffuse scattering, showed evidence of static, oxygen-vacancy induced atomic displacements along the 111 and other directions of the pseudo-cubic cell. DOE

MOCVD GROWTH AND STRUCTURE OF PbTiO3 THIN FILMS
Y. Gao (New Mexico Inst. of Mining and Technology, Socorro.), G. Bai, K. L. Merkle, H. L. M. Chang, and D. J. Lam Aug. 1993 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract W-31-109-eng-38)
(DE93-040230; ANL/MSD/CP-79239; CONF-930405-39) Avail: Issuing Activity (Department of Energy (DOE))

PbTiO3 thin films grown on (001)MgO and (110)MgO by MOCVD have been characterized by x-ray diffraction and transmission electron microscopy. The PbTiO3 films deposited on (001)MgO under the optimum conditions always show a bi-layer structure. The top layer of the films near the free surface is c-axis oriented with the orientation relationship (001) 100 PbTiO3 parallel (001) 100 MgO. The bottom layer of the films near the substrate is a-axis oriented with (100) 001 PbTiO3 parallel (001) 100 MgO. Ninety degree domains were observed, but only in the c-axis oriented layers. The thickness of the a-axis oriented layers near the substrate decreases with decreasing the cooling rate. PbTiO3 films deposited on (110) MgO, however, are single-layer, epitaxial films with (101) 001 PbTiO3 parallel (110) 001 MgO. DOE

THE EFFECT OF CORRELATED AND POINT DEFECTS ON THE VORTEX LATTICE MELTING TRANSITION IN SINGLE CRYSTAL YBa2Cu3O(7-DELTA)
W. K. Kwok, S. Fleshler, U. Welp, J. Downey, G. W. Crabtree, and J. Fendrich Aug. 1993 31 p Presented at the Conference of the International Union of Pure and Applied Physics on Low Temperature Physics (LT 20), Eugene, OR, 1-11 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-040277; ANL/MSD/CP-80634; CONF-930801-12) Avail: CASI HC A03/MF A01

The vortex melting transition T(sub m) in several untwinned and twinned crystals is measured resistively in fields up to 8 Tesla. A Lindemann criterion for vortex lattice melting is obtained in addition to a sharp hysteresis in the magnetoresistance at B(sub m) supporting a first order phase transition. The anisotropy of twin boundary pinning and its reduction of the 'kink' in (rho)(T) associated with the first order melting transition is discussed in samples with very dilute twin boundaries. We also report on direct suppression of melting transition by intrinsic pinning for H (parallel) ab and by electron-irradiation-induced point defects. DOE

HIGH OXYGEN PRESSURE SYNTHESIS OF NEW COPPER OXIDE SUPERCONDUCTORS
B. Dabrowski, V. Zhang-MacCoy, Z. Wang, R. Hannon, J. D. Jorgensen, B. A. Hunter, D. G. Hinks, J. L. Wagner, and R. L. Hitterman Aug. 1993 10 p Presented at the Physics and Chemistry of Molecular and Oxide Superconductors, Eugene, OR, 27-31 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-040278; ANL/MSD/CP-80635; CONF-930710-1) Avail: CASI HC A02/MF A01

The unique coordination of the copper ions in +1, +2, and +3 oxidation states which are stable in a range of oxygen partial pressure, 10(exp -6) less than P(O2) less than 10(exp 3) atm, makes possible the formation of a wide variety of distinct structures. By controlling the oxygen pressure during the synthesis and annealing, the distribution of metal- and oxygen ions can be modified on an atomic scale to optimize the structural and electronic properties. We present several examples of compounds for which the critical structural elements for superconductivity, i.e. the perfectly ordered CuO2-planes, have been obtained and doped with holes by means of high oxygen pressure, P(O2) greater than 1 atm. These materials, La22CuO(4+delta), La(2-x)Ca(x)CuO4 and YSr(2-x)La(x)Cu3O(7+delta) offer a unique opportunity to study the relationship between superconductivity and structural, magnetic, and chemical properties. DOE

TEMPERATURE-DEPENDENT ION BEAM MIXING
L. E. Rehn and D. E. Alexander Aug. 1993 8 p Presented at the International Union of Materials Research Societies on Advanced Materials, Tokyo, Japan, 31 Aug. - 4 Sep. 1993
(Contract W-31-109-eng-38)
(DE93-040281; ANL/MSD/CP-78737; CONF-9308122-4) Avail: CASI HC A02/MF A01

Recent work on enhanced interdiffusion rates during ion-beam mixing

at elevated temperatures is reviewed. As discussed previously, the expected increase in ion-beam mixing rates due to radiation-enhanced diffusion (RED), i.e. the free migration of isolated vacancy and interstitial defects, is well documented in single-crystal specimens in the range of 0.4 to 0.6 of absolute melting temperature. In contrast, the increase often observed at somewhat lower temperatures during ion-beam mixing of polycrystalline specimens is not well understood. However, sufficient evidence is available to show that this increase reflects intracascade enhancement of a thermally-activated process that also occurs without irradiation. Recent evidence is presented which suggests that this process is Diffusion-induced Grain-Boundary Migration (DIGM). An important complementary conclusion is that because ion-beam mixing in single-crystal specimens exhibits no significant temperature dependence below that of RED, models that invoke only irradiation-specific phenomena, e.g., cascade-overlap, thermal-spikes, or liquid-diffusion, and hence which predict no difference in mixing behavior between single- or poly-crystalline specimens, cannot account for the existing results. DOE

A QUANTITATIVE MODEL FOR INTERPRETING NANOMETER SCALE HARDNESS MEASUREMENTS OF THIN FILMS
W. H. Poisl, B. D. Fabes, and W. C. Oliver (Oak Ridge National Lab., TN.) 1993 8 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE93-040601; CONF-930405-40) Avail: CASI HC A02/MF A01

A model was developed to determine hardness of thin films from hardness versus depth curves, given film thickness and substrate hardness. The model is developed by dividing the measured hardness into film and substrate contributions based on the projected areas of both the film and substrate under the indenter. The model incorporates constraints on the deformation of the film by the surrounding material in the film, the substrate, and friction at the indenter/film and film/substrate interfaces. These constraints increase the pressure that the film can withstand and account for the increase in measured hardness as the indenter approaches the substrate. The model is evaluated by fitting the predicted hardness versus depth curves obtained from titanium and Ta2O5 films of varying thicknesses on sapphire substrates. The model is also able to describe experimental data for Ta2O5 films on sapphire with a carbon layer between the film and the substrate by a reduction in the interfacial strength from that obtained for a film without an interfacial carbon layer. TEMPERATURE DEPENDENCE OF CsI(Tl) GAMMA RAY EXCITED SCINTILLATION CHARACTERISTICS Ph.D. Thesis
1993 171 p
(Contracts DE-AC05-76OR-00033; DE-FG02-86NE-37969; DE-AC03-76SF-00098)
(DE94-000836; DOE/OR-00033/T542) Avail: CASI HC A08/MF A02

Gamma-ray excited emission spectrum, absolute scintillation yield, rise and decay time constants, and thermoluminescence emissions of CsI(Tl) were measured at -100 to +50 C, for crystals from 4 different vendors. The thermoluminescence glow curves were the only property that varied significantly from crystal to crystal; room temperature operation in current mode could be susceptible to temperature fluctuations. The CsI(Tl) emission spectrum has emission bands peaking around 400 and 560 nm; the former band disappears between -50 and -75 C. The RT absolute scintillation yield was calculated to be 65,500 +/- 4,100 photons/MeV. The two primary decay time constants increase exponentially with inverse temperature. An ultra-fast decay component was confirmed. Applications are discussed. DOE

N94-22035# Los Alamos National Lab., NM.
CRYSTAL ORIENTATION DEPENDENCE OF ELASTIC PRECURSOR STRENGTH IN PENTAERYTHRITOL TETRANITRATE
J. J. Dick, M. C. Whitehead, and A. R. Martinez 1993 5 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-36)
(DE93-018340; LA-UR-93-2343; CONF-930676-23) Avail: CASI HC A01/MF A01

Elastic precursor shock strengths were measured using VISAR instrumentation on pentaerythritol tetranitrate crystals 2.9 to 6.4 mm thick. Input shock strength was 1.2 GPa. A factor of 3 difference in elastic shock strength and a factor of 2 difference in critical resolved shear stress were observed depending on the crystal orientation. The order of increasing elastic shock strength was (100), (101), (110), and (001). This is the same order as that obtained in our analysis for increasing steric hindrance to shear, indicating that the relative strength of different orientations of this molecular crystal under shock conditions is governed by steric hindrance to shear. DOE

QUANTITATIVE ANALYSIS OF SCANNING TUNNELING MICROSCOPY IMAGES FOR SURFACE STRUCTURE DETERMINATION: SULFUR ON Re(0001)
D. F. Ogletree, J. C. Dunphy, M. B. Salmeron, and P. Sautet (Ecole Normale Superieure, Lyon, France.) Feb. 1993 15 p Presented at the OE/LASE 1993 SPIE Conference, Los Angeles, CA, 13-23 Jan. 1993
(Contract DE-AC03-76SF-00098)
(DE93-019235; LBL-33786; CONF-930159-54) Avail: CASI HC A03/MF A01

Scanning Tunneling Microscopy (STM) images of adsorbed atoms and molecules on single crystal substrates provide important information on surface structure and order. In many cases images are interpreted qualitatively based on other information on the system. To obtain quantitative information, a theoretical analysis of the STM image is required. A new method of calculating STM images is presented that includes a full description of the STM tip and surface structure. This method is applied to experimental STM images of sulfur adsorbed on Re(0001). Effects of adsorption site, adsorbate geometry, tip composition and tunnel gap resistance on STM image contrast are analyzed. The chemical identity of tip apex atom and substrate subsurface structure are both shown to significantly affect STM image contrast. DOE

A SPHEROMAK IGNITION EXPERIMENT REUSING MIRROR FUSION TEST FACILITY (MFTF) EQUIPMENT
T. K. Fowler 28 Sep. 1993 36 p

(Contract W-7405-eng-48)
(DE94-001856; UCRL-ID-114696) Avail: CASI HC A03/MF A01

Based on available experimental results and theory, a scenario is presented to achieve ohmic ignition in a spheromak by slow (approximately 10 sec.) helicity injection using power from the Mirror Fusion Test Facility (MFTF) substation. Some of the other parts needed (vacuum vessel, coils, power supplies, pumps, shielded building space) might also be obtained from MFTF or other salvage, as well as some components needed for intermediate experiments for additional verification of the concept (especially confinement scaling). The proposed ignition experiment would serve as proof of principle for the spheromak DT fusion reactor design published by Hagenson and Krakowski, with a nuclear island cost about ten times less than a tokamak of comparable power. Designs at even higher power density and lower cost might be possible using Christofilos' concept of a liquid lithium blanket. Since all structures would be protected from neutrons by the lithium blanket and the tritium inventory can be reduced by continuous removal from the liquid blanket, environmental and safety characteristics appear to be favorable. DOE

SIMULATING THE EUCLIDEAN TIME SCHROEDINGER EQUATIONS USING AN INTEL IPSC/860 HYPERCUBE: APPLICATION TO THE t-J MODEL OF HIGH-T(SUB c) SUPERCONDUCTIVITY
M. D. Kovarik and T. Barnes 1993 14 p Presented at the 6th Annual Workshop on Recent Developments in Computer Simulation Studies in Condensed Matter Physics, Athens, GA, 22-26 Feb. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000489; CONF-9302137-2) Avail: CASI HC A03/MF A01

We describe a Monte Carlo simulation of a dynamical fermion problem in two spatial dimensions on an Intel iPSC/860 hypercube. The problem studied is the determination of the dispersion relation of a dynamical hole in the t-J model of the high temperature superconductors. Since this problem involves the motion of many fermions in more than one spatial dimension, it is representative of the class of systems that suffer from the 'minus sign problem' of dynamical fermions which has made Monte Carlo simulation very difficult. We demonstrate that for small values of the hole hopping parameter one can extract the entire hole dispersion relation using the GRW Monte Carlo algorithm, which is a simulation of the Euclidean time Schroedinger equation, and present results on 4 x 4 and 6 x 6 lattices. Generalization to physical hopping parameter values will only require use of an improved trial wavefunction for importance sampling. DOE

(Contract W-7405-eng-36)
(DE94-000774; LA-UR-93-3333; CONF-930905-16) Avail: CASI HC A02/MF A01

The optical spectroscopy of the homoleptic U(IV) aryloxide compound U(O-2,6-t-Bu2C6H34 could give unique insight into actinide electronic structure because the complex has unusually high symmetry. Its synthesis and characterization were described in a recent paper. The characterization included presentation of several optical spectra in solution accompanied by a brief, qualitative discussion of the molecular properties that give rise to the observed features. This paper presents optical absorption data on microcrystalline solid samples at low temperature. Discussion of the data focuses generally on effect of the ligands on 5f2 electronic configuration of central U(IV) ion and specifically on properties of the ground state and the lowest lying electronic state. DOE

ORIENTATIONALLY INDEPENDENT ANTIFERROMAGNETIC COUPLING IN EPITAXIAL Fe/Cr (211) AND (100) SUPERLATTICES
E. E. Fullerton, M. J. Conover, J. E. Mattson, C. H. Sowers, and S. D. Bader Sep. 1993 13 p Presented at the 38th Annual Conference on Magnetism and Magnetic Materials, Minneapolis, MN, 15-18 Nov. 1993
(Contract W-31-109-eng-38)
(DE94-001270; ANL/MSD/CP-79906; CONF-931133-3) Avail: CASI HC A03/MF A01

We present structural and magnetic characterization of epitaxial Fe/Cr (211) and Fe/Cr (100) superlattices grown simultaneously on MgO (110) and MgO (100) substrates by magnetron sputtering. The epitaxial orientation of the Fe/Cr (211) superlattice with the MgO (110) substrates is Fe/Cr 0 bar-1 1 // MgO 001 and the orientation of Fe/Cr (100) is Fe/Cr 001 // MgO 011. We find that for both orientations, the interlayer coupling oscillates in sign with a period of 18 A and, furthermore, that the strength and phase of the magnetic coupling are also nearly identical for these two orientations. DOE

SPECTROSCOPIC STUDIES OF MAGNETIC TRANSITIONS IN TbPO4
G. K. Liu, C.-K. Loong, F. Trouw, M. M. Abraham (Oak Ridge National Lab., TN.), and L. A. Boatner (Oak Ridge National Lab., TN.) 1993 13 p Presented at the 38th Annual Conference on Magnetism and Magnetic Materials, Minneapolis, MN, 15-18 Nov. 1993
(Contracts W-31-109-eng-38; DE-AC05-84OR-21400)
(DE94-001274; ANL/CHM/CP-80906; CONF-931133-2) Avail: CASI HC A03/MF A01

Rare earth orthophosphates, RPO4 (R = Tb to Lu), crystallize in the tetragonal zircon structure in which R occupies sites of D(sub 2d) symmetry. The R = Tb, Dy, Ho compounds order antiferromagnetically at low temperature with the rare earth moments parallel to the crystallographic c-axis. In TbPO4 the magnetic transition is accompanied by a cooperative Jahn-Teller effect involving Tb ion-lattice coupling which induces a tetragonal to monoclinic distortion of the crystal lattice and a readjustment of the Tb electronic states as required by the lowering of the rare earth site symmetry. The laser excitation and emission spectra of TbPO4 and 0.1% Tb doped YPO4 single crystals were studied below and above the phase transition temperature. Line shapes of transitions in the stoichiometric compound are unusually broad and asymmetric whereas those for the dilute compound are sharp. The TbPO4 spectra show an anomalous temperature dependence near the phase transitions, indicating strong interactions of rare earth ions with environment. Comparison of the optical results with neutron scattering is made. DOE

TEST RESULTS OF TWO HIGH TEMPERATURE SUPERCONDUCTING SAMPLE COILS
J. W. Lue, S. W. Schwenterly, M. S. Lubell, J. N. Luton, C. H. Joshi, L. J. Masur, and E. R. Podtburg 1993 8 p Presented at the International Cryogenic Engineering and Material Conference, Albuquerque, NM, 12-16 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000496; CONF-930703-36) Avail: CASI HC A02/MF A01

Electrical measurements have been performed on two high temperature superconducting coils made by American Superconductor Corporation. One coil measured 24-mm ID, 59-mm OD, 50-mm long, and used 85-m long Y-124 tape conductor. The other coil measured 29-mm ID, 44-mm OD, 43-mm long, and used 35-m long Bi-2223 tape conductor. V-I curves were measured from room to helium temperature in a variable temperature cryostat cooled by helium gas in external fields up to 5 T. Without external field, the better performing Bi-2223 coil had a critical current, I(sub c) of 14.1 A (2820 A/sq cm over the conductor) at 4.2 K and 1.8 A (360 A/sq cm) at 77 K. At 5 T, I(sub c) was 4.9 A (980 A/sq cm) at 4.2 K and 2.0 A (400 A/sq cm) at 50 K. Reduced critical current, I(sub c)(B)/I(sub c)(0) vs field

plots indicated that a single smooth curve could fit all the data of up to 50 K in temperature. The reduction in critical currents with external fields for the Y-124 coil was more than 80% at 1 T. For the Bi-2223 coil, it was about 38% at 1 T and about 61% at 5 T. DOE

MELT-SPIN PROCESSING OF HIGH (Tc) OXIDE SUPERCONDUCTORS
T. J. Folkerts, Hengning Wu, S. I. Yoo, B. D. Merkle, S. R. Arrasmith, K. W. Dennis, M. J. Kramer, and R. W. McCallum 1993 4 p Presented at the 122nd Annual Meeting of the Minerals, Metals and Materials Society, Denver, CO, 21-25 Feb. 1993
(Contracts W-7405-eng-82; DE-FG02-90ER-45427)
(DE94-000696; IS-M-766; CONF-9302103-6) Avail: CASI HC A01/MF A01

Containerless techniques offer distinct advantages for the melt processing of oxide superconductors. The majority of these materials form liquids which are highly reactive with standard crucible materials such as Al2O3 and Pt, resulting in non-negligible contamination. We have developed a containerless melt-spin processing technique wherein 50-400 micron particles of REBa2Cu3O(7-x) high temperature oxide superconductors are melted in free fall through a vertical tube furnace and quenched onto a copper wheel. Previously this method has been successful in producing glasses of NdBa2Cu3O(7-x) and GdBa2Cu3O(7-x). In this report we discuss the results for both stoichiometric and non-stoichiometric YBa2Cu3O(7-x) (Y123). Thermal, microstructural, and superconducting characterization of both the as-quenched and the annealed materials will be presented. DOE

INITIAL OPERATION OF A LARGE-SCALE PLASMA SOURCE ION IMPLANTATION EXPERIMENT
B. P. Wood, I. Henins, R. J. Gribble, W. A. Reass, R. J. Faehl, M. A. Nastasi, and D. J. Rej 1993 20 p Presented at the Workshop on Plasma-Based Ion Implantation, Madison, WI, 4-6 Aug. 1993
(Contract W-7405-eng-36)
(DE94-000805; LA-UR-93-3216; CONF-9308156-2) Avail: CASI HC A03/MF A01

In Plasma Source Ion Implantation (PSII), a workpiece to be implanted is immersed in a weakly ionized plasma and pulsed to a high negative voltage. Plasma ions are accelerated toward the workpiece and implanted in its surface. Experimental PSII results reported in the literature have been for small workpieces. A large scale PSII experiment has recently been assembled at Los Alamos, in which stainless steel and aluminum workpieces with surface areas over 4 sq m have been implanted in a 1.5 m-diameter, 4.6 m-length cylindrical vacuum chamber. Initial implants have been performed at 50 kV with 20 micro-s pulses of 53 A peak current, repeated at 500 Hz, although the pulse modulator will eventually supply 120 kV pulses of 60 A peak current at 2 kHz. A 1,000 W, 13.56 MHz capacitively-coupled source produces nitrogen plasma densities in the 10(exp 15) m(exp -3) range at neutral pressures as low as 0.02 mtorr. A variety of antenna configurations have been tried, with and without axial magnetic fields of up to 60 gauss. Measurements of sheath expansion, modulator voltage and current, and plasma density fill-in following a pulse are presented. The authors consider secondary electron emission, x-ray production, workpiece arcing, implant conformality, and workpiece and chamber heating. DOE

ALLOYING STUDIES IN U(1-x)Th(x)Pd2Al3 (0 (le) X (le) 1)
Y. Dalichaouch (California Univ., San Diego.) and M. B. Maple 1993 7 p Presented at the International Conference on Strongly Correlated Electronic Systems, San Diego, CA, 15-19 Aug. 1993
(Contracts W-7405-eng-36; DE-FG03-86ER-45230)
(DE94-000807; LA-UR-93-3143; CONF-9308173-3) Avail: CASI HC A02/MF A01

Measurements of temperature and concentration dependences of magnetic susceptibility and electrical resistivity for U(1-x)Th(x)Pd(2)Al(3) are presented. The magnetic susceptibility data scale with the concentration of U ions over large regions of x and T. The electrical resistivity shows a smooth evolution from the Kondo lattice regime to the single ion Kondo behavior as Th concentration x is increased. A lack of saturation in resistivity in the samples with x = 0.8 and 0.6, and a logarithmic divergence in (chi)(T) at low temperatures makes the U(1-x)Th(x)Pd2Al3 system a good candidate for a two-channel Kondo effect. DOE

POSITRON ANNIHILATION STUDY OF Sr DOPING IN La(2-x)Sr(x)CuO4
P. A. Sterne, R. H. Howell, M. J. Fluss, and J. H. Kaiser (Texas Univ., Arlington.) 22 Apr. 1993 10 p Presented at the Conference on Spectroscopies in Novel Superconductors, Santa Fe, NM, 17-19 Mar. 1993 (Contract W-7405-eng-48)
(DE94-000307; UCRL-JC-112045; CONF-930367-10) Avail: CASI HC A02/MF A01

A combined experimental and threshold study of effects of Sr doping on electronic structure of La(2-x)Sr(x)CuO(4) was presented. Electron-positron momentum distributions were measured to high statistical precision (greater than 4 x 10(exp 8) counts) at room temperature for samples with Sr concentrations of x = 0.0, 0.1, 0.13, and 0.2. Analysis of all four spectra reveal strong features due to electron-positron wavefunction overlap, in quantitative agreement with theoretical calculations. The Sr doped samples show discontinuities consistent with presence of a Fermi surface. The form and position of these features are in general agreement with the predictions of band theory. Correspondence between theory and experiment, as well as some differences, are revealed by a detailed study of the changes in electron-position momentum density with increasing Sr doping. DOE

It is shown that the two dimensional gravity, described either in the conformal gauge (Liouville theory) or in the light cone gauge, when coupled to matter processes an infinite number of twisted N = 2 superconformal symmetries. The central charges of the N = 2 algebra for the two gauge choices are in general different. Further, it is argued that the physical states in the light cone gauge theory can be obtained from the Liouville theory by a field redefinition. DOE

THE THERMODYNAMIC PROPERTIES TO 700 K OF NAPHTHALENE AND 2,7-DIMETHYLNAPHTHALENE
R. D. Chirico, S. E. Knipmeyer, A. Nguyen, and W. V. Steele Aug. 1993 57 p
(Contract DE-FC22-83FE-60149)
(DE93-000160; NIPER-678) Avail: CASI HC A04/MF A01

Measurements leading to the calculation of the ideal-gas thermodynamic properties are reported for naphthalene and 2,7-dimethylnaphthalene. Experimental methods included adiabatic heat-capacity calorimetry, vibrating-tube densitometry, comparative ebulliometry, and differential-scanning calorimetry (d.s.c.). The critical temperature and critical density were determined experimentally for each compound and the critical pressures were derived from fitting procedures. Vapor-pressure measurements reported in the literature were compared with the results obtained in this research. Enthalpies of vaporization and sublimation were derived from the experimental measurements and compared with literature results. New self-consistent equations for the variation of sublimation pressure with temperature for naphthalene and 2,7-dimethylnaphthalene were derived. Literature values for entropies and enthalpies of the liquid phases and energies of combustion were combined with the present results to derive entropies, enthalpies, and Gibbs energies of formation for the ideal gases for selected temperatures between 298.15 K and 700 K. The ideal-gas properties for naphthalene were compared with values obtained using statistical mechanics with various fundamental vibrational frequency assignments available in the literature. A scheme to estimate the ideal-gas thermodynamic functions for alkylnaphthalenes was updated. The barrier to methyl-group rotation in 2,7-dimethylnaphthalene was shown to be of the same order of magnitude as that published for toluene. Values for ideal-gas entropies for 2-methylnaphthalene in the temperature range 300 K to 700 K were estimated. DOE

A FORMULATION OF QUANTUM STATISTICAL MECHANICS BASED ON THE FEYNMAN PATH CENTROID DENSITY 2 DYNAMICAL PROPERTIES Technical Report No. 6, May 1993 - 1994
Jianshu Cao and Gregory A. Voth 4 Nov. 1993 41 p
(Contract N00014-92-J-1243)
(AD-A272698) Avail: CASI HC A03/MF A01

The formulation of quantum dynamical time correlation functions is examined within the context of the path centroid variable in Feynman path integration. This study builds upon the centroid-based approach to equilibrium properties developed in the companion paper. The introduction of the centroid perspective into the calculation of real time position functions is outlined and intriguing quasiclassical role for the centroid variable in real time position correlation functions is identified. The centroid-based theory is then implemented in several different approaches to calculate general correlation functions. The theoretical results are illustrated and tested by representative numerical applications. DTIC

A FORMULATION OF QUANTUM STATISTICAL MECHANICS BASED ON THE FEYNMAN PATH CENTROID DENSITY 1: EQUILIBRIUM PROPERTIES Technical Report, May 1993 - 1994
4 Nov. 1993 44 p
(AD-A272809) Avail: CASI HC A03/MF A01

A formulation of quantum statistical mechanics is presented in which the Feynman path centroid density in Feynman path integration is recast as the central statistical distribution used to average equilibrium and dynamical quantities. In this formulation, the path integral centroid density occupies the same role as the Boltzmann density in classical statistical mechanics. Therefore, the statistical ensemble of imaginary time path centroid configurations provides the distribution which is used to average the appropriately formulated effective operators and imaginary time correlation functions. An accurate renormalized diagrammatic perturbation theory for the centroid density and centroid-constrained imaginary time

propagator is also described with a particular emphasis given to the mathematical advantages arising from the centroid-based formulation. The present paper is concerned with the calculation of equilibrium properties from the centroid perspective, while the companion paper describes a centroid-based formalism for calculating dynamical time correlation functions. The ultimate thermodynamic cost of computing from x to y is investigated. Such research has implications for future miniaturization of VLSI (Very Large Scale Integration) chips reducing the energy dissipation below kT (thermal noise) and the similarity problem in pattern recognition. The theory of thermodynamic cost of computation turns out to be possible to develop axiomatically. The theorem connects physics to mathematics and establishes optimal upper and lower bounds on the ultimate thermodynamic cost of computation. ESA

ON THE CORRESPONDENCE LIMIT OF RELATIVISTIC QUANTUM MECHANICS
H. P. Noyes May 1993 6 p Presented at the 1993 Symposium on the Foundations of Modern Physics, Cologne, Germany, 1-6 Jun. 1993
(Contract DE-AC03-76SF-00515)
(DE93-040939; SU-SLAC-Pub-6010; CONF-9306255-1) Avail: CASI HC A02/MF A01

One of the many problems of second quantized relativistic field theory is that the 'correspondence limit' either in non-relativistic quantum mechanics for atomic systems or in non-relativistic quantum mechanics for strongly interacting nuclear systems or in classical relativistic particle mechanics is not well specified. In this paper we argue that by using a fully finite and discrete approach to relativistic quantum mechanics we can arrive at a theory which does not have these defects, yet reproduces many of the same empirical results which are conventionally accounted for in any elementary particle physics and the related physical cosmology. DOE

RESTORING LOCALITY WITH FASTER-THAN-LIGHT VELOCITIES
P. H. Eberhard 30 Aug. 1993 8 p Presented at the Waves and Particles in Light and Matter Conference, Trani, Italy, 24-30 Sep. 1992
(Contract DE-AC03-76SF-00098)
(DE93-040926; LBL-34575; CONF-9209407-1) Avail: CASI HC A02/MF A01

The idea of 'locality' is a deep rooted concept. It does not have to be abandoned even if 'loophole free' EPR experiments are performed and confirm the predictions of quantum theory. To satisfy locality, one can imagine that influences at a distance are exerted via mechanisms involving an ether and effects propagating in that ether a velocity V greater than c. Such model of physical phenomena is not Lorentz invariant but, with V large enough, the model can be made to reproduce the results of all experiments where quantum mechanics and Lorentz invariance have been verified. NASA'S EDUCATION PROGRAM
Sep. 1993 66 p
(NASA-EP-297; NAS 1.19:297) Avail: CASI HC A04/MF A01

NASA's current education programs, which will be examined under its Strategic Plan for Education are presented. It is NASA's first goal to maintain this base - revising, expanding, or eliminating programs as necessary. Through NASA's second goal, new education reform initiatives will be added which specifically address NASA mission requirements, national educational reform, and Federal Coordinating Council for Science, Engineering, and Technology (FCCSET) priorities. The chapters in this publication are divided by educational levels, with additional sections on programs to improve the technological competence of students and on an array of NASA published materials to supplement programs. The resource section lists NASA's national and regional Teacher Resource Centers and introduces the reader to NASA's Central Operation of Resources for Educators (CORE), which distributes materials in audiovisual format.

FEMALE SECURITY AS A GENERAL MOBILITY CONDITION Ph.D. Thesis [DIE SICHERHEIT VON FRAUEN ALS ALLGEMEINE MOBILITAETSBEDINGUNG]
Carola Jeschke 1993 227 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISBN-3-79-831536-1; ETN-93-95064) Avail: CASI HC A11

Female specific attitudes before jeopardy and threats and their influence on female mobility are examined from an engineering point of view. Feelings such as fear, anxiety, which women can experience, and their consequences on female behavior towards mobility, are reviewed with statistical information and enquiry results, and are examined from the viewpoint of traffic safety. The choice of limited mobility of women as a preventive measure was considered. Situations which influence subjective and objective security on the street or in collective transport vehicles and criteria of outer spaces for positive security feelings are depicted. Concepts for taking safety principles into account in the traffic planning are presented. Strategies for improvement of traffic conditions are proposed. ESA

NASA PROPERTY: IMPROVING MANAGEMENT OF GOVERNMENT EQUIPMENT PROVIDED TO CONTRACTORS. REPORT TO THE CHAIRMAN, SUBCOMMITTEE ON INVESTIGATIONS AND OVERSIGHT, COMMITTEE ON SCIENCE, SPACE, AND TECHNOLOGY, HOUSE OF REPRESENTATIVES
Sep. 1993 56 p
(GAO/NSIAD-93-191; B-253482) Avail: CASI HC A04/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

NASA has provided billions of dollars of government-owned personal property to its contractors for use on research and development, production, and service contracts. The value of government personal property, especially general purpose equipment, provided to contractors has grown substantially in recent years despite the government policy to minimize providing equipment to contractors. The Chairman, Subcommittee on Investigations and Oversight, House Committee on Science, Space, and Technology, requested that the General Accounting Office (GAO) review NASA property management activities. Specifically, GAO's objectives were to determine NASA's compliance with federal regulations intended to minimize the amount of government-owned, contractor-held general purpose equipment; the effectiveness of government and contractor controls over equipment; and the adequacy of NASA's reporting of this equipment. NASA PROCUREMENT: PLANNING FOR PILOT TEST OF NEW PROCUREMENT PROCEDURES IS ADEQUATE. REPORT TO THE CHAIRMAN, COMMITTEE ON GOVERNMENTAL AFFAIRS, US SENATE
Nov. 1993 14 p
(GAO/NSIAD-94-67; B-254647) Avail: CASI HC A03/MF A01; also available from GAO, PO Box 6015, Gaithersburg, MD 20877 HC

This document reports on a review of the National Aeronautics and Space Administration's planning for a pilot test of new procedures for procurements with annual values between $25,000 and $500,000 and total 5-year values up to $2.5 million. NASA refers to these procurements as 'mid-range' procurements. The purpose of the pilot test is to determine if the new procedures will reduce the time and effort required to solicit offers and award contracts in this price range. As currently designed, each midrange acquisition of supplies or services shall be reserved exclusively for small business concerns. Specifically, the review covered the extent to which the pilot test procurement procedures differ from the Federal Acquisition Regulation (FAR); the development of key features of the pilot project, including the financial impact of using an electronic commerce system on those wanting to do business with NASA and how such a system would provide for amending solicitations; and NASA's plans for assessing the results of the pilot project. A GUIDE TO RESOLVING DISPUTES OVER CONTRACTOR DELAY ENTITLEMENTS M.S. Thesis
Michael J. Clark Dec. 1993 92 p
(AD-A272022) Avail: CASI HC A05/MF A01

This thesis presents criteria to resolve disputes over contractor entitlement for delay damages with a detailed examination of the enforceability of the no-damage-for-delay clause. Appellate case law identifies the rules applied by the courts in these disputes. These rules of application were organized into a flowchart format to give contract administrators and other construction professionals an understanding of how the no-damage-for-delay clause has been interpreted. The intent is for contract administrators to resolve their disputes without going to court. The thesis also states the rules of application for resolving disputes over site access delays prior to commencing construction. Finally, the thesis explains the significance of the time-is-of-the-essence clause, as it relates to delay disputes. DTIC

NASA PROCUREMENT REPORT, FY 1992 Semiannual Report, 1 Oct. 1991 - 31 Mar. 1992

1992 30 p

(NASA-TM-109390; NAS 1.15:109390) Avail: CASI HC A03/MF A01

This report presents summary data on all NASA procurement actions and detailed information on contracts, grants, agreements, and other procurements over $25,000 awarded by NASA during the first six months of Fiscal Year 1992. The dollar value on procurements over $25,000 amounted to 98 percent of the total dollar value of procurement actions completed during the first six months of Fiscal Year 1992. However, these larger procurements accounted for only 29 percent of the total actions. Procurement action, as used in this report, means contractual actions to obtain supplies, services, or construction which increase or decrease funds. A procurement action thus may be a new procurement, or modifications such as supplementary agreements, change orders, or terminations to a contract that change the total amount of funds obligated.

NASA PROCUREMENT REPORT, FY 1993 Annual Report

1993 53 p

(NASA-TM-109393; NAS 1.15:109393) Avail: CASI HC A04/MF A01

Summary data on all NASA procurement actions and detailed information on contracts, grants, agreements, and other procurements over $25,000 awarded by NASA during fiscal year 1993. The dollar value on procurements over $25,000 amounted to 97 percent of the total dollar value of procurement actions completed during fiscal year 1993. However, these larger procurements accounted for only 29 percent of the total actions. Procurement action, as used in this report, means contractural actions to obtain supplies, services, or construction which increase or decrease funds. A procurement action thus may be a new procurement, or modifications such as supplemental agreements, change orders, or terminations to an existing contract that change the total amount of funds obligated. An obligation is a contractual commitment to pay for supplies or services that are specified in the contract. Derived from text

FACTORS ASSOCIATED WITH CONTINUANCE COMMITMENT TO FAA MATRIX TEAMS Final Report

Chan M. Hellman (Union Carbide Corp., La Mesa, CA.), Lawrence Alan Witt (Barnett Banks, Inc., OK.), and Thomas F. Hilton Nov. 1993 9 p

(DOT/FAA/AM-93/18) Avail: CASI HC A02/MF A01

Several organizations within the FAA employ matrix teams to achieve cross-functional coordination. Matrix team members typically represent different organizational functions required for project accomplishment (e.g., research and development, engineering, quality assurance, legal, acquisition, and customers). The matrix team strategy decentralizes decision-making to the level of a project leader, so that knowledge relevant to the decision can be collected and outcomes closely monitored. While there are several factors that influence productivity of matrix teams, member turnover can have a substantial impact. Thus, identifying the factors that affect a productive member's continued membership to the team is important. Data gathered as part of a research task initiated at the request of the Associate Administrator for NAS Development (AND-1) is summarized. Questionnaires were developed to evaluate how well existing AND matrix teams were functioning. These data will also serve as a baseline against which to gage future development of the matrix team program. Two issues were examined: the relationship between perceptions of the quality of member-team interactions and individual member commitment to remain on the team (continuance commitment) and, whether or not that relationship might be influenced by the degree to which a member identified with the team as opposed to his/her individual office, function, or profession. Results from 141 members of 22 FAA matrix teams indicated a significant relationship between the quality of member-team interactions and continuance commitment. Moreover, team identification moderated the magnitude of the relationship between interaction quality and continuance commitment. Specifically, regardless of team identification, when members perceived member-team interactions to be of high quality, they also reported commitment to continuing on the team. However, this relationship was particularly critical for those members whose identification with the team was weak. For them, the quality of interactions among team members was strongly related to continuance commitment. Based on these results, efforts by project leaders to increase the number of and quality of interactions between matrix team members and to encourage member identification with the team are likely to reduce unwanted turnover behaviors.

SUMMARY DATA ON ALL NASA PROCUREMENT ACTIONS Annual Procurement Report, FY 1992

1992 53 p

(NASA-TM-109392; NAS 1.15:109392) Avail: CASI HC A04/MF A01

This report presents summary data on all NASA procurement actions and detailed information on contracts, grants, agreements, and other procurements over $25,000 awarded by NASA during Fiscal Year 1992 (FY-92). The dollar value on procurements over $25,000 amounted to 97 percent of the total dollar value of procurement actions completed during FY-92. However, these larger procurements accounted for only 28 percent of the total actions. Procurement action, as used in this report, means contractual actions to obtain supplies, services, or construction which increase or decrease funds. A procurement action thus may be a new procurement or modifications such as supplemental agreements, change orders, or terminations to an existing contract that change the total amount of funds obligated. An obligation is a contractual commitment to pay for supplies or services that are specified in the contract. Author (revised)

MODELLING DECISION-MAKING BY PILOTS Progress Report

Nicholas J. M. Patrick 13 Dec. 1993 28 p

(Grant NAG2-729)

(NASA-CR-194767; NAS 1.26:194767) Avail: CASI HC A03/MF A01

Our scientific goal is to understand the process of human decision-making. Specifically, a model of human decision-making in piloting modern commercial aircraft which prescribes optimal behavior, and against which we can measure human sub-optimality is sought. This model should help us understand such diverse aspects of piloting as strategic decision-making, and the implicit decisions involved in attention allocation. Our engineering goal is to provide design specifications for (1) better computer-based decision-aids, and (2) better training programs for the human pilot (or human decision-maker, DM). SISSY: AN EXAMPLE OF A MULTI-THREADED, NETWORKED, OBJECT-ORIENTED DATABASED APPLICATION
B. Scipioni, D. Liu, and T. Song May 1993 8 p Presented at the 5th Annual International Industrial Symposium on the Super Collider and Exhibition, San Francisco, CA, 6-8 May 1993
(Contract DE-AC35-89ER-40486)
(DE93-019742; SSCL-Preprint-321; CONF-930537-101) Avail: CASI HC A02/MF A01

The Systems Integration Support System (SISSY) is presented and its capabilities and techniques are discussed. It is a fully automated data collection and analysis system supporting the SSCL's systems analysis activities as they relate to the Physics Detector and Simulation Facility (PDSF). SISSY itself is a paradigm of effective computing on the PDSF. It uses home-grown code (C++), network programming (RPC, SNMP), relational (SYBASE) and object-oriented (ObjectStore) DBMS's, UNIX operating system services (IRIX threads, cron, system utilities, shells scripts, etc.), and third party software applications (NetCentral Station, Wingz, DataLink) all of which act together as a single application to monitor and analyze the PDSF. EXPLAINABLE EXPERT SYSTEMS: A RESEARCH PROGRAM IN INFORMATION PROCESSING Final Report
Cecile L. Paris 1993 29 p
(Contract NCC2-520)
(NASA-CR-193422; NAS 1.26:193422) Avail: CASI HC A03/MF A01

Our work in Explainable Expert Systems (EES) had two goals: to extend and enhance the range of explanations that expert systems can offer, and to ease their maintenance and evolution. As suggested in our proposal, these goals are complementary because they place similar demands on the underlying architecture of the expert system: they both require the knowledge contained in a system to be explicitly represented, in a high-level declarative language and in a modular fashion. With these two goals in mind, the Explainable Expert Systems (EES) framework was designed to remedy limitations to explainability and evolvability that stem from related fundamental flaws in the underlying architecture of current expert systems. A PROPOSED RESEARCH PROGRAM IN INFORMATION PROCESSING Final Technical Report, 1 Nov. 1987 - 30 Sep. 1992
Herbert Schorr 1992 10 p Sponsored in part by DOD and DARPA
(Contract NCC2-520)
(NASA-CR-194271; NAS 1.26:194271) Avail: CASI HC A02/MF A01

The goal of the Formalized Software Development (FSD) project was to demonstrate improvements productivity of software development and maintenance through the use of a new software lifecycle paradigm. The paradigm calls for the mechanical, but human-guided, derivation of software implementations from formal specifications of the desired software behavior. It relies on altering a system's specification and rederiving its implementation as the standard technology for software maintenance. A system definition for this paradigm is composed of a behavioral specification together with a body of annotations that control the derivation of executable code from the specification. Annotations generally achieve the selection of certain data representations and/or algorithms that are consistent with, but not mandated by, the behavioral specification. In doing this, they may yield systems which exhibit only certain behaviors among multiple alternatives permitted by the behavioral specification. The FSD project proposed to construct a testbed in which to explore the realization of this new paradigm. The testbed was to provide operational support environment for software design, implementation, and maintenance. The testbed was proposed to provide highly automated support for individual programmers ('programming in the small'), but not to address the additional needs of programming teams ('programming in the large'). The testbed proposed to focus on supporting rapid construction and evolution of useful prototypes of software systems, as opposed to focusing on the problems of achieving production quality performance of systems. LOW BIT RATE CODING OF EARTH SCIENCE IMAGES
Faouzi Kossentini, Wilson C. Chung, and Mark J. T. Smith [1993] 10 p
(Grant NAG5-2187)
(NASA-CR-193729; NAS 1.26:193729) Avail: CASI HC A02/MF A01

In this paper, the authors discuss compression based on some new ideas in vector quantization and their incorporation in a sub-band coding framework. Several variations are considered, which collectively address many of the individual compression needs within the earth science community. The approach taken in this work is based on some recent advances in the area of variable rate residual vector quantization (RVQ). This new RVQ method is considered separately and in conjunction with sub-band image decomposition. Very good results are achieved in coding a variety of earth science images. The last section of the paper provides

some comparisons that illustrate the improvement in performance attributable to this approach relative the the JPEG coding standard.

A SCSI-BUS DATA ACQUISITION SYSTEM FOR NUCLEAR SPECTROSCOPY EXPERIMENTS
B. Hovander, A. Johansson, G. Appelquist, and C. Bohm Sep. 1992 16 p
(USIP-92-03; ETN-93-94846) Avail: CASI HC A03/MF A01

An IBM-386 personal computer controlled data acquisition system which uses the Small Computer System Interface (SCSI) bus as a system bus is described. The SCSI bus choice makes it easy to attach commercially available mass storage devices such as Video-8 or Digital Audio Tape (DAT). The system was developed for nuclear physics applications but may be modified. The design is based on programmable components such as an embedded micro controller and a field programmable gate array. The data acquisition system serves in its present form 15 NIM standard Analog to Digital Converters (ADC's), but will be updated to accommodate more units. The data acqusition system is also equipped with a monitor function where the main data path to the storage device is diverted to a monitor interface in the system controller. Implementation details and flow charts are presented. ESA

[DEVELOPMENT OF A NAMING CONVENTION AND DATA MA NAGEMENT SYSTEM] Final Report, 24 Dec. 1987 - 15 Nov. 1992
Richard T. McNider, Michael Botts, Don Moss, Helen Conover, Evan Criswell, Sara Graves, and Danny Hardin 1993 107 p
(Contract NAS8-37139)
(NASA-CR-193860; NAS 1.26:193860) Avail: CASI HC A06/MF A02

This contract covered work in data management, acquisition, and analysis for the Earth Science and Applications Division (ESAD) of the Space Science Laboratory of MSFC. Under this contract, a naming convention and data management system were developed for ESAD data sets, data visualization, and standard data format issues were investigated, and specific data analysis and management needs were addressed for several ESAD projects and data sets. In the following sections, details of the research performed over the duration of this contract are summarized.

THE MANAGER'S GUIDE TO NASA GRAPHICS STANDARDS
[1980] 18 p
(NHB-1430.2; NAS 1.18:1430.2) Avail: CASI HC A03/MF A01

NASA managers have the responsibility to initiate and carry out communication projects with a degree of sophistication that properly reflects the agency's substantial work. Over the course of the last decade, it has become more important to clearly communicate NASA's objectives in aeronautical research, space exploration, and related sciences. Many factors come into play when preparing communication materials for internal and external use. Three overriding factors are: producing the materials by the most cost-efficient method; ensuring that each item reflects the vitality, knowledge, and precision of NASA; and portraying all visual materials with a unified appearance. This guide will serve as the primary tool in meeting these criteria. This publication spells out the many benefits inherent in the Unified Visual Communication System and describes how the system was developed. The last section lists the graphic coordinators at headquarters and the centers who can assist with graphic projects. By understanding the Unified Visual Communication System, NASA managers will be able to manage a project from inception through production in the most cost-effective manner while maintaining the quality of NASA communications.

HERMES, A REPORT GENERATOR FOR RESEARCH ON INFORMATION PROCESSING IN COMMAND POSTS: THE EFFECT OF MISSING INFORMATION Final Report [HERMES: EEN BERICHTENGENERATOR VOOR ONDERZOEK NAAR INFORMATIEVERWERKING IN COMMANDOPOSTEN; HET EFFECT VAN ONTBREKENDE INFORMATIE]
J. H. Kerstholt and J. E. T. Mathijssen Feb. 1993 24 p In DUTCH
(Contract A89/KL/309)
(IZF-1992-A-28; TD-92-2290; ETN-94-94925) Avail: Issuing Activity (TNO Institute for Perception, Kampweg 5, 3769 DE Soesterberg, Netherlands)

A computer program HERMES (Hierarchical Enemy Reports from Multiple Sensors), which can generate intelligence reports of sensors signaling vehicle movements within a prespecified range, is described. At present the messages are based on one sensor only. The simulator HERMES is designed for experimental purposes and offers the possibility to manipulate the output (for example the number of messages) of the simulation. Based on reports generated with HERMES the effects of missing information on the quality of recognizing the 'order of battle' was investigated. The results of previous research were replicated: on low command levels, less units were identified when 30% of the information was missing. On higher and more global performance levels, no effects of information reduction were found. It is concluded that HERMES can be used for further research, especially for the evaluation of man-computer systems in controlled, suboptimal task environments. ESA

RECOMMENDATIONS RESULTING FROM THE SPDS COMMUNITY-WIDE WORKSHOP
1993 17 p Workshop held in Houston, TX, 1-3 Jun. 1993
(Grant NAG5-2264; SwRI Proj. 15-5659)
(NASA-CR-194684; NAS 1.26:194684) Avail: CASI HC A03/MF A01

The Data Systems Panel identified three critical functionalities of a Space Physics Data System (SPDS): the delivery of self-documenting data, the existence of a matrix of translators between various standard formats (IDFS, CDF, netCDF, HDF, TENNIS, UCLA flat file, and FITS), and a network-based capability for browsing and examining inventory records for the system's data holdings. The recommendations resulting from the workshop include the philosophy, funding, and objectives of a SPDS. Access to quality data is seen as the most important objective by the Policy Panel, with curation and information about the data being integral parts of any accessible data set. The Data Issues Panel concluded that the SPDS can supply encouragement, guidelines, and ultimately provide a mechanism for financial support for data archiving, restoration, and curation. The Software Panel of the SPDS focused on defining the requirements and priorities for SPDS to support common data analysis and data visualization tools and packages. Derived from text

AN ASSESSMENT OF THE STATISTICAL AND EDITORIAL OUTPUT OF TEXT ANALYSIS PROGRAMS Final Report, Feb. - Oct. 1992
Paul H. Radtke Oct. 1993 31 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272185; NPRDC-TN-94-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study assessed commercially available text analysis programs for their accuracy and usefulness to novice writers. Two topics were examined: the reliability and accuracy of scores and indicators, and the level and validity of the editorial comments. Six text analysis programs were assessed by comparing their output for two previously published Navy technical publications. The analyzers produced different word and sentence counts, and standard readability scales, suggesting that each uses different algorithms to analyze text material. The analyzers' statistical measures may be sensitive to the complexity and format of text samples, but not to their size. The analyzers varied on the number and level of comments, the validity of the comments, and the types of problems they detect. The text analyzers are able to detect problems of usage, sentence length, and other low-level mistakes. They are less able to detect problems involving the relationship between parts of sentences. Specific problems created by the unique characteristics of technical writing are identified (e.g., technical terminology, passive sentence forms, numbers). The analyzers assessed in this study are suitable to supplement, but not replace, traditional editing. If accompanied by additional guidance, they might be used as tutorial aids. DTIC

MULTI WAVE LINK: AN INTERACTIVE DATABASE FOR CO-ORDINATION OF MULTIWAVELENGTH PROGRAMS Final Report, 1 Oct. 1989 - 30 Sep. 1993

France Cordova 30 Sep. 1993 7 p

(Grant NAGw-1920)

(NASA-CR-194778; NAS 1.26:194778) Avail: CASI HC A02/MF A01

Multi Wave Link is an operational database used by the international astronomical community to plan and coordinate multiwavelength observational campaigns on various celestial objects. This facility has been and continues to be an essential tool for the organization of numerous simultaneous ground-based and satellite observations. The Multi Wave Link system has both an interactive component and an electronic mail alert notice component. The interactive portion contains a database of schedules from several of the world's larger observatories and orbiting satellites. Lists of observers, observatories, and their available instrumentation are additionally contained in the system. Another feature added to the software allows the user to search the Royal Greenwich Observatory e-mail listing of international astronomers. This capability is often used by astronomers to find the electronic address of colleagues for improved communication. However, the most productive aspect of the Multi Wave Link system appears to be one of the simplest parts of the system: the electronic mail alert notices for observing campaigns. Information useful in planning the structure of future astronomical databases can be obtained by studying patterns of use of the Multi Wave Link system. This paper analyzes 22 months of Multi Wave Link usage from Sep. 1991 - Jul. 1993. Derived from text

ON THE SELECTION OF INDICES IN RELATIONAL DATABASES

Sunil Choenni, Henk Blanken, and Thiel Chang (Gemeenschappelijk Administratiekantoor, Amsterdam, Netherlands.) 18 Nov. 1992 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Memo-INF-92-72; ETN-93-94114) Avail: CASI HC A03

Topics relating to index selection in data bases are addressed. Intending to develop a tool which aims to support the physical design of relational data bases can not be done without considering the problem of index selection. Generally the problem is split into a primary and secondary index selection problem and the selection is done per table. Whereas much attention has been paid on the selection of secondary indices relatively less is known about the selection of a primary index and the relation between primary and secondary index selection. The primary index selection and secondary index selection problem are shown to be mutually independent. Two heuristic methods for solving the index selection problem are described and compared. Some rules of thumb used to determine candidate primary indices are evaluated. An attempt was made to improve existing heuristics. The methodology used in implementing the tool for supporting physical database design is described. ESA

PERFORMANCE MANAGEMENT SYSTEMS: A STATISTICAL ANALYSIS M.S. Thesis

James W. Kilby Sep. 1993 78 p

(AD-A272989) Avail: CASI HC A05/MF A01

This study assessed the performance management systems used by companies, in an effort to identify the evolution of new management techniques in corporations. The sample consisted of 119 individual survey respondents from 'high performing' entities. The data collected was part of a luger performance measurement study conducted by Euske, Lebas and McNair (1993). 'High performing' entities were identified by the management of companies included in this study. Companies selected for the study were identified by the CAM-I research consortia or directly identified by Euske, Lebas or McNair. DTIC

DEVELOPMENT AND OPERATIONS OF THE ASTROPHYSICS DATA SYSTEM Semiannual Report Nos. 1 and 2

S. S. Murray Nov. 1993 214 p

(Contract NCCw-24)

(NASA-CR-194691; NAS 1.26:194691) Avail: CASI HC A10/MF A03

The main effort in October 1992 was for the development and of the Astrophysics Data System (ADS) 3.1 graphical interface (GUI) and the preparation for its release. The beta-release for the GUI was made available to the nodes for testing. Development of the Abstract Server progressed satisfactorily. A test version was prepared for the ADASS meeting. Another major effort was the preparation for the user and nodes meetings on 5 and 6 November and for the ADASS conference on 2-4 November. February 1993 was highlighted by the preparation for the update release and its associated problems. We have the okay from the Commerce Department to export ADS. Foreign users can now sign on and receive the software. The main event during June was the AAS meeting. In the summer, the project decided on a new release schedule. The next major release is scheduled for January 1994 and will include major architectural improvements. In late spring 1994, a major release will include the new networking software. LIGHT UPDATE NOTIFICATION MECHANISM FOR SHARED DATA STRUCTURES Patent

Carlos M. Tavares, inventor (to Navy) 21 Sep. 1993 8 p Filed 3 Oct. 1991

(AD-D015967; US-Patent-5,247,684; US-Patent-Appl-SN-770207; US-Patent-Class-395-700) Avail: US Patent and Trademark Office

A system for updating and reading a data base utilizes a pair of counters working in conjunction with registers located within RAM to enable one upon reading the data base to know if a data base record has been added, deleted, or revised. The system also notifies if the data base is being updated on attempting a read process or during the reading. The updating is performed by a writer that is never inhibited from updating the data base. DTIC

PROMISES AND FAULT-TOLERANT DATABASE ACCESS

Jin-Yi Cai (Princeton Univ., NJ.), Lane A. Hemachandra, and Jozef Vyskoc (Slovak Academy of Sciences, Bratislava, Czechoslovakia.) Apr. 1993 47 p

(Grants NSF CCR-90-57486; NSF CCR-89-57604; NSF INT-91-16781; NSF

(TR-447) Avail: CASI HC A03/MF A01

This paper studies the power of access, especially fault-tolerant access, to probabilistic databases and to unambiguous databases . We study fault-tolerant access to probabilistic computation, and completely characterize the complexity classes R and ZPP in terms of fault-tolerant database access. We also show that consistent and inconsistent failure are in general interchangeable. We study the power of three types of access to unambiguous computation: nonadaptive access, fault-tolerant access, and guarded access. Though for NP it is known that nonadaptive access has exponentially terse adaptive simulations, we show that UP has no such relativizable simulations: there are worlds in which k + 1-truth-table access to UP is not subsumed by k-Turing access to UP, or even to NP machines that are unambiguous on the questions actually asked. Though fault-tolerant access (i.e., '1-helping' access) to NP is known to be no more powerful than NP itself, we give both structural and relativized evidence that fault tolerant access to UP suffices to recognize even sets beyond UP. Furthermore, we completely characterize, in terms of locally positive reductions, the sets that fault-tolerantly reduce to UP. In guarded access, Grollmann and Selman's natural notion of access to unambiguous computation, a deterministic polynomial-time Turing machine asks questions to a nondeterministic polynomial-time Turing machine in such a way that the nondeterministic machine never accepts ambiguously. In contrast to guarded access, the standard notion of access to unambiguous computation is that of access to a set that is uniformly unambiguous--even for queries that it never will be asked by its questioner, it must be unambiguous. We show that these notions, though the same for nonadaptive reductions, differ for Turing and strong nondeterministic reductions. Author (revised)

INTEGRATION OPPORTUNITIES FOR COMPUTER MODELS, METHODS, AND GIS USED IN CORPS PLANNING STUDIES
Roger T. Kilgore, Joseph S. Krolak, and Mark P. Mistichelli Feb. 1993 114 p
(Contract DACW72-90-D-0001)
(AD-A271714; IWR-93-R-5) Avail: CASI HC A06/MF A02

The report surveys models, methods and geographic information systems (GIS) used in water resources planning by the Corps of Engineers and suggests opportunities for integrating these tools to improve planning and decision-making. Information on models, methods and GIS was gathered via completed planning studies, a literature survey and interviews with planners and researchers at Corps laboratories other technical centers and District offices. An inventory of planning tools discovered during the information-gathering process is included in the report. The report identifies several issues that will affect the integration of planning tools, including the difficulty of matching the needs of the user with the tool, data issues, hardware/software choices and organizational concerns. The report offers four strategies for approaching integration: (1) development of interfaces for existing models, methods and GIS; (2) incorporation of spatial functions into models; (3) incorporation of modeling functions into GIS; and (4) development of Spatial Decision Sup Systems (SDSS). Each strategy can be effective although the SDSS approach has considerable merit in addressing Corps planning problems. The report concludes with a description of general activities that should be undertaken by the Corps to facilitate the integration of planning tools for water resources decision-making. DTIC

CMIFed: A PRESENTATION ENVIRONMENT FOR PORTA BLE HYPERMEDIA DOCUMENTS
Guido vanRossum, Jack Jansen, K. Sjoerd Mullender, and Dick C. A. Bulterman Jan. 1993 14 p Presented at ACM Multimedia 1993 Conference Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-CS-R9305; ETN-94-94734) Copyright Avail: CASI HC A03

The architecture and implementation of CMIFed, an editing and presentation environment for hypermedia documents, are discussed. Typically such documents contain a mixture of text, images, audio, and video (and possibly other media), augmented with user interaction. CMIFed allows the author flexibility in specifying what is presented when by using multiple simultaneous output channels. Unlike systems that use a timeline or scripting metaphor to control the presentation, in CMIFed the user manipulates a collection of events and timing constraints among those events. Common timing requirements can be specified by grouping events together in a tree whose nodes indicate sequential and parallel composition. More general timing constraints between events can be added in the form of synchronization arcs. User interaction is supported in the form of hyperlinks. CMIFed is placed in the context of the CMIF (CWI Multimedia Interchange Format) model for hypermedia documents, which formalizes the properties of hypermedia presentations in a platform independent manner. ELECTRONIC RESOURCES FOR SECURITY RELATED INFORMATION: REFERENCE DOCUMENT
R. A. Feingold May 1993 40 p Presented at the Westinghouse Information Security Form Conference, Baltimore, MD, 13-14 May 1993
(Contract W-7405-eng-48)
(DE93-040488; UCRL-JC-113857; CONF-9305284-1) Avail: CASI HC A03/MF A01 (US Sales Only)

The quantity, quality, and availability of electronic resources is multiplying rapidly. Information technology security professionals must make timely and effective use of these resources if they are to contain the growing threats of globally networked attackers. This paper outlines the threats, including recent examples, and then provides multi-level descriptions of the abundant resources available to the information technology security community. These descriptions are valuable to everyone from a networking novice to a sophisticated expert. While the information is useful for the entire security community, this paper pays particular attention to Department of Energy requirements. DOE

STRUCTURED MULTIMEDIA AUTHORING
Lynda Hardman, Guido vanRossum, and Dick C. A. Bulterman Jan. 1993 15 p Presented at ACM Multimedia 1993 Conference Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-CS-R9304; ETN-94-94733) Copyright Avail: CASI HC A03

The user interface to the CMIF (CWI (Centrum voor Wiskunde en Informatica) Multimedia Interchange Format) authoring environment for constructing and playing multimedia presentations is presented. The CMIF authoring environment supports a rich hypermedia document model allowing structure based composition of multimedia presentations and the specification of synchronization constraints between constituent media items. An author constructs a multimedia presentation in terms of its structure and additional synchronization constraints, from which the CMIF player derives the precise timing information for the presentation. The advantages of a structured approach to authoring multimedia are discussed and facilities in the CMIF authoring environment for supporting this approach are described. The

authoring environment presents three main views of a multimedia presentation: the hierarchy view is used for manipulating and viewing a presentation's hierarchical structure; the channel view is used for managing logical resources and specifying and viewing precise timing constraints; and the player for playing the presentation. The authoring environment is presented in terms of a short example: constructing a walking tour of Amsterdam. ESA

THE AMSTERDAM HYPERMEDIA MODEL: EXTENDING HYPERTEXT TO SUPPORT REAL MULTIMEDIA
Lynda Hardman, Dick C. A. Bulterman, and Guido vanRossum Jan. 1993 19 p Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-CS-R9306; ETN-94-94735) Copyright Avail: CASI HC A03

A model of hypermedia that allows the combination of 'hyperstructured' information with dynamic multimedia information is presented. The model is derived by extending the Dexter hypertext reference model and the CMIF (CWI Multimedia Interchange Format) multimedia model. The Amsterdam hypermedia model allows the following, in addition to the model provided by Dexter: the composition of multiple dynamic media, in order to specify a collection of time based media making up a complete multimedia presentation; the definition of 'channels' for specifying default presentation information allowing the specification of the presentation characteristics of nodes at a more general level than that for an individual node; the composition of existing presentations into larger presentations taking into account possible clashes of resource usage; the inclusion of temporal relations while maintaining the separation of structure and presentation information, where time based relationships are treated as presentation information; and the specification of 'context' for anchors, in order to determine whether on following a link a part, or the whole, of the presentation is replaced by the information at the destination of the link. The Amsterdam hypermedia model enables the description of structured multimedia documents, incorporating time at a fundamental level, and extending the hypertext notion of links to time based media and compositions of different media. The Dexter hypertext model and the CMIF multimedia model are summarized, and their limitations for use as a more general hypermedia model are discussed. The extensions included in the Amsterdam hypermedia model are described and a summary of the resulting model is given. ESA

ASSESSMENT OF THE ORGANIZATIONAL STRUCTURE AND SERVICES OF DOE NATIONAL LABORATORY LIBRARIES
Kathy Dieden (San Jose State Univ., CA.) 18 May 1993 27 p
(Contract W-7405-eng-48)
(DE93-040697; UCRL-ID-114069) Avail: CASI HC A03/MF A01

This fieldwork assignment was created to assess the library and information services at the National Laboratories and to understand their organizational structures and the role of the library within those structures. The author's goal was to collect the data and to evaluate the data and make appropriate recommendations for improving the quality of service at Lawrence Livermore National Laboratory Library. The objectives were: to develop a questionnaire which will be used in the reference interview; to contact a knowledgeable staff person at each facility and collect the information services data from that person; to identify innovative and unique services; to identify non-traditional methods of delivering information services to the scientific clientele; to obtain any user feedback on the services provided; and to identify the organization structure of each of the National laboratories and to determine the role of the library within those structures. DESIGN DOCUMENT AND DATABASE SPECIFICATIONS FOR THE NAVAL INTERACTIVE DATA ANALYSIS SYSTEM (NIDAS), VERSION 1.0
Dharmesh Krishnamagaru 29 Oct. 1993 60 p
(Contract NAS13-564)
(NASA-CR-194817; NAS 1.26:194817; AD-A273056; CAST-TN-01-94)
Avail: CASI HC A04/MF A01

The purpose of this document is to define and describe the structural framework and logical design of the software components/units which willbe integrated into the major computer software configuration item (CSCI) identified as the Naval Interactive Data Analysis System (NIDAS), Version 1.0. NIDAS provides interactive blending and overlaying capabilities for a broad range of environmental data types and formats. The final product output of NIDAS is three-dimensional gridded fields of temperature and salinity, constructed from data derived by the user internally within NIDAS and data obtained from external sources (numerical models, observations, and climatological databases). PROJECT RECORDS INFORMATION SYSTEM (PRIS): USER'S MANUAL
R. K. Schwarz, ed. Oct. 1993 72 p
(Contract DE-AC05-84OT-21400)
(DE94-001548; K/CSD/TM-93-Rev-2) Avail: CASI HC A04/MF A01

The Project Records Information System (PRIS) is an interactive system developed for the Information Services Division (ISD) of Martin Marietta Energy Systems, Inc., to perform indexing, maintenance, and retrieval of information about engineering project record documents for which they are responsible. This PRIS User's Manual provides instruction on the use of this system. Section 2.0 of this manual presents an overview of PRIS, describing the system's purpose; the data that it handles; functions it performs; hardware, software, and access; and help and error functions. Section 3.0 describes the interactive menu-driven operation of PRIS. Appendixes A, B, and C contain help screens, report descriptions, and the data dictionary, respectively. DOE

ACCESS TO D3-D DATA LOCATED IN MULTIPLE FILES AND MULTIPLE LOCATIONS
B. B. McHarg, Jr. Oct. 1993 5 p Presented at the Symposium on Fusion Engineering, Hyannis, MA, 11-15 Oct. 1993
(Contract DE-AC03-89ER-51114)
(DE94-001104; GA-A-21404; CONF-931018-18) Avail: CASI HC A01/MF A01

The General Atomics DIII-D tokamak fusion experiment is now collecting over 80 MB of data per discharge once every 10 min, and that quantity is expected to double within the next year. The size of the data files, even in compressed format, is becoming increasingly difficult to handle. Data is also being acquired now on a variety of UNIX systems as well as MicroVAX and MODCOMP computer systems. The existing computers collect all the data into a single shot file, and this data collection is taking an ever increasing amount of time as the total quantity of data increases. Data is not available to experimenters until it has been collected into the shot file, which is in conflict with the substantial need for data examination on a timely basis between shots. The experimenters are also spread over many different types of computer systems (possibly located at other sites). To improve data availability and handling, software has been developed to allow individual computer systems to create their own shot files locally. The data interface routine PTDATA that is used to access DIII-D data has been modified so that a user's code on any computer can access data

from any computer where that data might be located. This data access is transparent to the user. Breaking up the shot file into separate files in multiple locations also impacts software used for data archiving, data management, and data restoration. DOE

IMPLEMENTATION OF A LABORATORY INFORMATION MANAGEMENT SYSTEM FOR ENVIRONMENTAL REGULATORY ANALYSES
W. A. Spencer, H. B. Aiken, T. L. Spatz, W. F. Miles, and J. C. Griffin Sep. 1993 80 p Presented at the 34th ORNL/DOE Conference on Analytical Chemistry in Energy Technology, Gatlinburg, TN, 5-7 Oct. 1993
(Contract DE-AC09-89SR-18035)
(DE94-001198; WSRC-MS-93-390; CONF-931081-1) Avail: CASI HC A05/MF A01

The Savannah River Technology Center created a second instance of its ORACLE based PEN LIMS to support site Environmental Restoration projects. The first instance of the database had been optimized for R&D support and did not implement rigorous sample tracking, verification, and holding times needed to support regulatory commitments. Much of the R&D instance was transferrable such as the work control functions for backlog reports, work assignment sheets, and hazard communication support. A major enhancement of the regulatory LIMS was the addition of features to support a 'standardized' electronic data format for environmental data reporting. The electronic format, called 'AN92', was developed by the site environmental monitoring organization and applies to both onsite and offsite environmental analytical contracts. This format incorporates EPA CLP data validation codes as well as details holding time and analytical result reporting requirements. The authors support this format by using special SQL queries to the database. The data is then automatically transferred to the environmental databases for trending and geological mapping. DOE

ELIMINATING AMORTIZATION: ON DATA STRUCTURES WITH GUARANTEED RESPONSE TIME Ph.D. Thesis
Rajeev Raman Oct. 1992 95 p
(Contract N00014-82-K-0193)
(TR-439) Avail: CASI HC A05/MF A01

An efficient amortized data structure is one that ensures that the average time per operation spent on processing any sequence of operations is small. Amortized data structures typically have very non-uniform response times; i.e., individual operations can be occasionally and unpredictably slow, although the average time over the sequence is kept small by completing most of the other operations quickly. This makes amortized data structures unsuitable in many important contexts, such as real-time systems, parallel programs, persistent data structures and interactive software. On the other hand, an efficient (single-operation) worst-case data structure guarantees that every operation will be processed quickly. The construction of worst-case data structures from amortized ones is a fundamental problem which is also of pragmatic interest. Progress has been slow so far, both because the techniques used were of a limited nature and because the resulting data structures had much larger hidden constant factors. Both these issues are addressed. Author (revised)

INFORMATION TECHNOLOGY AND ECONOMIC MODELLING
Pentti Uuspaeae, ed. and Goeran Pulkkis, ed. (Helsinki Univ. of Technology, Espoo, Finland.) 1992 311 p Presented at Joint Finnish-Soviet Symposium, Helsinki, Finland, 20-22 Nov. 1990
(VTT-SYMP-135; ISBN-95-1384-086-7; ETN-93-94486) Copyright Avail: CASI HC A14/MF A03

Papers presented at a symposium to promote cooperation between Finnish and Soviet scientists, engineers, and economists by examining developments in information technology and economic modeling are presented. The papers are organized into the following working sessions: macroeconomic models, economic modeling, computer software and hardware, applied computing, economic modeling methods, operations research, data systems and technology, and economic evaluation. For individual titles, see N94-22057 through N94-22087.

SYSTEM ARCHITECTURES FOR BANKING APPLICATIONS **c82**
Kalevi Kontinen *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 11-21 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

A discussion on system architectures for banking applications based on the experience of a Finnish bank is presented. In order to perform their society mission with quality and efficiency, banks need many resources and skills. Together with human competence and vision, data processing systems are the basis and key resource of modern banking. Production and development costs of information processing may exceed 15% of nonfinancial expenses of bank. Heavy investigating is no guarantee of success in data processing. Smarter, not larger spending makes the difference of good and mediocre systems. Right applications must be automated in the right way, buying the resources for the right price. Essential parts in the right way of doing things are the basic structural choices of systems and their architectures. ESA

A discussion on informatization in Soviet society is presented. The program of informatization is oriented towards the transition to the regulated market economy as well as the creation of the conditions necessary to achieve social and economic development aims. An outline of what the program should provide is given. The state program of informatization includes the following sections: use of ITE (Information Technology Equipment) in national economy; informatization infrastructure; ITE development and production; organization and economic support of informatization processes; and macroeconomic indices of informatization. ESA

MATHEMATICAL MODELLING OF ECONOMIC SYSTEMS
Alexander A. Petrov *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 39-52 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

The main propositions of the general approach to mathematical description and analysis of economic systems are presented. This approach was developed in the U.S.S.R. as the system analysis of evolving economy. The basic equations of mathematical models in frames of the system analysis of evolving economy are displayed. The problem of closing this system of equations by means of modeling of goods production, exchange and distribution process control relations is discussed. Some results of market economy are also discussed. ESA

N94-22061# Technical Research Centre of Finland, Espoo.
AJKA: AN ECONOMETRIC MACROMODEL FOR FINLAND
Asko Korpela *In its* Information Technology and Economic Modelling 1992 p 53-63 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

The structure, utilization, performance, equations and data of the AJKA Keynesian demand oriented equilibrium econometric macromodel are outlined. AJKA is being employed on personal computers for forecasting and policy optimization in educational context. The model was found to be a well working backbone of an intermediate course in macroeconomics, allowing the students to become acquainted with the structural relationships of the national economy and the connection of basic theories and their empirical application. The model was also used in management training. ESA

MACROMODEL OF CENTRALLY PLANNED ECONOMY
Alexander P. Krutov *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 64-73 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A02/MF A03

A mathematical description of production, exchanges, distribution and consumption processes in the centrally planned economy is suggested. Information disposed by the planning center is described as well as planning procedures by it. Their influence on economic self adjustment mechanisms is analyzed. Some results of computer experiments are presented. ESA

N94-22063# Tampere Univ. of Technology (Finland).
INFORMATION AND DECISION STRUCTURE IN A JAPANESE TYPE OF MANAGEMENT WITH RESPECT TO QCC AND JUST-IN-TIME SYSTEMS **c82**
Ilari Tyrni *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 74-75 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A01/MF A03

The requirements for the efficiency of Quality Control Circles (QCC) and Just-In-Time (JIT) systems are considered. The requirements of teamwork can be more generally considered instead of QCC for the proper organization of information and decision making systems. Even from the point of view of QCC and JIT, the optimal information and decision structure is not independent of the other structures of the firm. This is especially important with regard to the education and training of employees. Also the incentive structure (images, promotion, and other factors) must be such that it motivates QCC and JIT activities. ESA

COMPUTER-AIDED DESIGN SYSTEM FOR OBJECTS LOCATION AND RESERVOIR WITH DISPERSED RESOURCE EVOLUTION INVESTIGATION **c61**
S. V. Tuev *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 76-84 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A02/MF A03

A program intended for multiversional calculations of object location and reservoir evolution is reported. Objects are oriented for collection and manufacturing of resources dispersed on any reservoir. Reservoir evolution is also taken into account. The software is based on algorithms for representation of geographical information and dispersed resource distribution, algorithms giving information about the territory heterogeneity and its resources, algorithms solving a complex of objects allocation by distributed resource problems, and on algorithms analyzing the objects with dispersed resource (reservoir) evolution model. The expert can use the software to form effective projects of facility location. ESA

THE PROGRAM SYSTEM FOR THE DIAGNOSTICS OF STRAINS AND FRACTURE PREDICTION OF SOLIDS **c39**
V. Z. Parton and V. Boriskovski *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 85 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A01/MF A03

An expert system for fracture mechanics based assessment of structure lifetime is reported. The main design and operation features are outlined. The stress intensity factor computation for typical flaws is based on the weight function method. It allows the calculation efficiency to be improved and the numerous body configurations to be analyzed. In design, the part-through flaw shape is calculated (from the stable crack shapes). In service, the possibility is provided for the stress intensity factor computational and nominal stress assessment in the crack plane from discrete Crack Opening Displacement (COD) values at an essential distance from the crack tip. The J-, C*-, and COD-based fracture assessment methods are used in accordance with R6 standard. The failure assessment diagrams are derived with the use of a multiparametric approach. The crack growth prediction involves the evaluated criteria of transforming test results from standard specimens to structures with part-through cracks. The relationships of the so called small crack growth are also taken into account. Numerous applied problems for industry, power engineering, in particular, were solved. ESA

APPLICATION DEVELOPMENT IN A PC/LAN ENVIRONMENT Abstract Only **c61**
Kurt Helenelund *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 93 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A01/MF A03

As the drive towards the desktop accelerates, the delivery of vertical business applications and mission critical applications on the desktop becomes critical. The networked systems will emerge as the main application platform not just for traditional personal productivity applications but also for workgroup solutions and corporate mission critical systems. The new generation of applications will be based on the client/server model, and they will use graphical user interfaces. Database servers using the SQL standard will emerge as the dominating information warehouse on PC LAN's (Personal Computer Local Area Networks). As the demand for easy to use applications increases, developers are faced with a situation where more and more time is spent on the design and implementation of the user interface. In most modern applications, a major part of the developed code is spent on the user interface with current technology. ESA

THE DISTRIBUTED CAD SYSTEM FOR LSI/VLSI DESIGN **c61**
V. G. Zacharov and V. A. Konyavsky *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 94-100 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A02/MF A03

Peculiarities of microelectronic CAD (Computer Aided Design) are conditioned by a wide assortment of design objects. Computer capacities necessary to carry on design processes vary with the class of the object (PLD's, Gate-Arrays, submicron technology custom VLSI (Very Large Scale Integration), etc.) as well as with design stages. For example, while performance of a PC (Personal Computer) is quite sufficient for circuit input or logical synthesis of nodes etc., a supercomputer's performance might not provide capacity for some technology simulation or circuitry modeling. This variety of requirements to be satisfied constrains the design of a distributed mode system. The structure of a distributed, multiple user CAD system for LSI/VLSI design is envisaged, while considering the demands to provide necessary peak capacities to perform variable information flow processing. Setting up a number of centers integrated into a regional computer net is envisaged by the USSR state informatization program to provide the structure implementation. Problems of hardware choice as well as those of choice of basic and application software are examined. ESA

IAS TELECOMMUNICATION INFRASTRUCTURE AND VALUE ADDED NETWORK SERVICES PROVIDED BY IASNET **c32**
Oleg L. Smirnov and Sergei Marchenko *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 101-119 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

The topology of a packet switching network for the Soviet National Centre for Automated Data Exchange with Foreign Computer Networks and Databanks (NCADE) based on a design by the Institute for Automated Systems (IAS) is discussed. NCADE has partners all over the world: it is linked to East European countries via telephone lines while satellites are used for communication with remote partners, such as Cuba, Mongolia, and Vietnam. Moreover, there is a connection to the Austrian, British, Canadian, Finnish, French, U.S. and other western networks through which users can have access to databases on each network. At the same time, NCADE provides western customers with access to more than 70 Soviet databases. Software and hardware of IASNET use data exchange recommendations agreed with the International Standard Organization (ISO) and International Telegraph and Telephone Consultative Committee (CCITT). Technical parameters of IASNET are compatible with the majority of foreign networks such as DATAPAK, TRANSPAC, TELENET, and others. By means of IASNET, the NCADE provides connection of Soviet and foreign users to information and computer centers around the world on the basis of the CCITT X.25 and X.75 recommendations. Any information resources of IASNET and value added network services, such as computer teleconferences, E-mail, information retrieval system, intelligent support of access to databanks and databases, and others are discussed. The topology of the ACADEMNET connected to IASNET over an X.25 gateway is also discussed. ESA

INDUSTRY STANDARDS: KEY TO DISTRIBUTED COMPUTING **c62**
Ari Mikkola *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 120-133 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

A major trend during the 1990's will be a continued downsizing and distribution of computing resources. This trend is fuelled by rapid development of PC (Personal Computer), workstation, and communications technologies which bring cost effective processing power on the desktop. An intelligent workstation is a user's window to the services of the entire distributed information system. Data stored in different computers is available to be shared by applications in other computers. The emphasis in distributed computing will be first on intracompany connectivity and access to public services and later on intercompany connectivity. Open industry standards play an important role. The standardization trends which are relevant to distributed computing in the areas of connectivity and interoperability, portability, and user access, are discussed. ESA

AN ECONOMIC ANALYSIS OF TRANSBOUNDARY AIR POLLUTION BETWEEN FINLAND AND THE SOVIET UNION Abstract Only **c45**
Veijo Kaitala, Matti Pohjola (Research Inst. of the Finnish Economy, Helsinki.), and Olli Tahvonen (Helsinki School of Economics and Business Administration, Finland.) *In* Technical Researh Centre of Finland, Information Technology and Economic Modelling 1992 p 147 (For primary document see N94-22056 05-83)
(ETLA-Discussion-Paper-335) Copyright Avail: CASI HC A01/MF A03

An evaluation of the net benefits to both parties of bilateral cooperation between Finland and the Soviet Union on reducing sulphur emissions is presented. The analysis is based on a sulphur transportation model and on estimated abatement cost functions. It is shown that efficient cooperation may entail financial transfers from Finland to the Soviet Union because it is cheaper to abate sulphur there. It is further demonstrated that the recently signed agreement aiming at reductions in air pollutants is not rational from the Soviet Union's viewpoint and may not, therefore, be carried out without monetary support from Finland. ESA

MULTICRITERIA OPTIMISATION PROBLEM IN THE AGRICULTURAL MODELLING **c43**
H. M. Stoliarova *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 148-161 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

A multicriteria optimization problem concerning crop production is considered. Optimal strategies for winter wheat production (the principal

crop of the Stavropol region of the USSR) are determined on the base of the dynamic crop weather simulation models. Approximation of Pareto set for two criteria and different strategies of fertilizer application was constructed. As a result, reasonable compromising solutions were identified which could serve as a useful tool for agricultural planning in the Stavropol territory and in other semi arid regions. ESA

ANALYSIS OF CONSUMER DEMAND STRUCTURE BY MEANS OF ECONOMIC INDEXES
A. A. Shananin *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 162-172 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

A nonparametric method for calculation of economic indexes, that are positive homogeneous utility function (index of product) and price index, is considered. The economic indexes calculated by this method reflect the structure of consumer demand functions and may be used for the solution of the following problems: to predict the changing of demand structure when prices change; to find the ratio of prices which is necessary to support some consumer demand structure. ESA

A MODEL OF NEGOTIATION IN AN EXTENSIVE FORM GAME **c66**
Ivan Menshikov *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 173-181 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A02/MF A03

Any game theoretical equilibrium is not effective as a social choice function. In general, the equilibrium is not Pareto optimal. So, it is reasonable to consider an improvement of the original game associated with negotiation. A comparison of several known approaches to game theoretical research of negotiation is presented. A problem of axiomatic characterization of a negotiation mechanism is discussed. The most attractive applications of this idea correspond to extensive form games. Re-negotiation of two different types is considered: talks at the initial position of the game and those at one of the next positions when, after disagreement, somebody makes a move in the original game. A number of unexpected features of that model are represented. ESA

CONTROLLING MULTISUPPLIER OPERATIONS BY INTELLIGENT EDI **c32**
Juha Eskelinen, Jyrki Kovanen, Miika Linna, Tero Mononen, and Reijo Sulonen *In* Technical Research Centre of Finland, Information Technology and Economic Modelling 1992 p 182-205 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

In modern CIM (Computer Integrated Manufacturing) environment, problems that can affect production should be discovered as soon as possible. This can be very difficult in multisupplier operations where problems outside one organization can remain undetected until they already have effects inside that organization. If Electronic Data Interchange (EDI) is used to control intercompany operations there is a better possibility to detect problems on logistic chain. Because these problems usually have some effects in the flow of EDI messages, they can be detected by controlling this flow. A Forget-Me-Not (FMN) system, which is a programmable message management system that can control the flow of EDI messages and detect exceptional situations is discussed. ESA

APPLICATION OF THE STRUCTURES QUERY LANGUAGE OF APROS FOR SPECIFICATION OF INDUSTRIAL PROCESSES **c61**
Kaj Juslin *In its* Information Technology and Economic Modelling 1992 p 213-225 (For primary document see N94-22056 05-83)
Copyright Avail: CASI HC A03/MF A03

The development of a structured query language for specification of industrial processes is reported. The intention was to provide a tool for process design engineers for building a computerized model of the process studied, without having to learn how to solve differential equations, or without programming in any general simulation or high level language. This complies with the goals of the fifth generation software, to bring the user interface between hardware and user much closer to the concepts of user. The language has also proved to be useful in definition of the simulation experiments to be made, including model extent, initial conditions, duration of experiment, and variables to be plotted. ESA

In a computer network data are stored at the different sites of the network. An application running in one computer can access data stored at a different site. The data thus constitute a distributed database. Many problems are faced when building and implementing such a distributed database. The structure of the database, that is, how the data are distributed, must be carefully planned. In order to do that, the interdependencies among data in a distributed system and the analysis of the particular data to be distributed must be understood. The most central issues encountered when planning a database in a distributed environment are discussed. ESA

The architecture, algorithms, and user friendly interface employed in three original programs for managers are described: SCAN MAN (optical character recognition system), Window eDitor (word processor system), and Teleman (business schedule system). Full time interval used to input and recognize one A4 page of 2000 character Russian/English test by MSF-300C scanner and 12 MHz PC/AT or compatible (without co-processor) using SCAN MAN program equals approximately one minute. In this case, the number of mistakes cannot exceed 0.5 as a rule. Window eDitor is a powerful and simple integrated system. Window eDitor has a compact executive module, easy command set, and powerful tools for block/windows operations. The following additional functions are used in the system: recoder; efficient file support subsystem; simultaneous use of several alphabets, for example Russian, English, and Georgian; simple and original storage and preparation of business papers; and pseudo multidimensional spreadsheet. Teleman includes the following subsystems: business schedule which makes it possible to itemize a task, to make an appointment or phone call for any day, and to review, correct, or print records; built-in structurized subscriber database; business card directories; and exchange of information with Casio B.O.S.S. pocket notebook, etc. ESA

Copyright Avail: CASI HC A02/MF A03

Experiences on a simulation model of the Finnish economy consisting of about 270 equations are reported. The research team produces at least four business cycle forecasts each year and evaluates economic policy alternatives over a horizon of 3 to 10 years. It is seen to be of vital importance to ensure that the model is consistent and its structure well understood by the users. It is therefore useful to start the construction of a large model from a well defined set of first general principles and to work 'downwards' to practical solutions without breaking the a priori defined structure of the system. Second, it is necessary to keep the models sufficiently simple and quick to use. Although the models must of course evolve in parallel with the actual policy issues, the pressure to expand the size of the model too much with rarely needed detail must be resisted. Thirdly, the fact that the behavioral patterns of people and firms are not invariant over time must be considered. ESA

An approach to public problems investigation is suggested. This approach provides conditions for discussions informing public opinion about potential results of the decision making. The approach presented is based on the so called generalized reachable sets (GRS) method. The method itself is quite universal and can be used for many purposes, but in the case when the economic system's performance indicators (objectives) are given the GRS method provides a tool for multi-objective evaluation of the system's potential possibilities. This publication is intended to foster the aim of the NASA Technology Transfer Program by heightening awareness of the NASA technology available for reapplication and its potential for public benefit. The publication is organized in three main sections. Section 1 outlines NASA's mainline effort, the major programs that generate new technology and therefore replenish and expand the bank of knowledge available for transfer. Section 2 contains a representative sampling of spinoff products that resulted from secondary application of technology originally developed to meet mainline goals. Section 3 describes the various mechanisms NASA employs to stimulate technology transfer and lists, in an appendix, contact sources for further information about the Technology Transfer Program.

THE X RAY HALO OF AM HER Final Report

Richard C. Catura 4 Aug. 1993 6 p

(Contract NAS5-31223)

(NASA-CR-189310; NAS 1.26:189310) Avail: CASI HC A02/MF A01

The objective of this research was to study the halo surrounding the ROSAT image of the cataclysmic variable AM Her that is formed by scattering of x-rays by interstellar dust grains. AM Her was in a low state of x-ray emission during the 14,400 sec observation and thus an insufficient number of counts were obtained to detect the x-ray halo. Author

The longest pointed observation (152 ksec) with the Rosat position sensitive proportional counter in the direction of the absolutely lowest neutral hydrogen column density is discussed. 26 shallower fields from the Rosat medium sensivity survey are analyzed. 1176 X-ray sources were detected in at least one Rosat energy band in these fields covering a total solid angle of 9.3 deg; 661 of these sources constitute a statistically complete sample detected in the hard band with 0.5 to 2 keV fluxes greater than 2.5 times 10 to the power of minus 15 erg/sq cm s. The faintest limiting flux of the survey is analyzed. Detailed simulations show that confusion effects and other selection biases are relatively small and can be corrected for in the sample. From an analysis in the Lockman field, a best fit slope of approximately 1.8 is found for the extrapolation of the differential X-ray counts below 2.5 times 10 to the power of minus 15 erg/sq cm s. On the basis of this analysis an upper limit of approximately 25% can be found for a truly diffuse background component in the Rosat hard band. ESA

Copyright Avail: CASI HC A03/MF A01

Images of X-ray emission from hot gas within the Coma cluster of galaxies are presented. These maps, made with the Rosat satellite, have high signal to noise ratio and allow cluster structure to be analyzed in unprecedented detail. They show greater structural irregularity than could be anticipated from earlier observations of Coma. Emission is detected from a number of bright cluster galaxies in addition to the two known previously. In four cases there is evidence that these galaxies lie at the center of an extended subconcentration within the cluster, possibly the remnant of their associated groups. For at least two galaxies the images

show direct evidence for ongoing disruption of their gaseous atmosphere. The luminosity associated with these galaxies is comparable to that detected around similar ellipticals in much poorer environments. Emission is easily detected and appears to become more regular at large radii. The data show that this archetype of a rich and regular galaxy cluster was formed by the merging of several distinct subunits which are not yet fully destroyed. ESA

FOCUS HISTORY OF THE HUBBLE SPACE TELESCOPE: LAUNCH TO MAY 1993
H. Hasan, C. J. Burrows (European Space Agency, Washington, DC.), and D. J. Schroeder (Beloit Coll., WI.) 10 Sep. 1993 46 p
(Contract NAS5-26555)
(NASA-CR-194179; NAS 1.26:194179) Avail: CASI HC A03/MF A01

Since the launch of the Hubble Space Telescope (HST) the secondary mirror of the telescope has been moved several times in order to collimate the telescope and also to define a position of best focus. In addition to these moves the focus position changes over time because of water desorption by the graphite epoxy in the metering truss. The authors report here the focus history of the telescope based on a knowledge of the mirror moves made and an analysis of desorption monitoring data obtained by the Faint Object Camera (FOC) in the F/96 mode and of the routine calibration data obtained by the Wide Field and Planetary Cameras. Focus values are extracted using two different methods. In the first method the distance between the center of the point spread function (PSF) and the shadows of the pads supporting the HST primary mirror are related to the focus error. In the second method an analytical formula for the PSF with variable aberration coefficients is fitted to the data. Focus positions derived from the two methods show good agreement. The data show that a desorption of about 83 microns has taken place since Aug. 16, 1990. The desorption has clearly not leveled off as expected from the trend of the earlier data. Long term variations of the secondary mirror position of approximately 3-15 microns from the 'best' focus position have been observed. Variations of the order of 2-5 microns over an orbital period have also been noted. Focus changes resulting from secondary mirror movements greater than approximately 5 microns changes the point spread function significantly and makes deconvolution and quantitative measurements difficult. HIGH-ENERGY ASTROPHYSICS: A THEORETICAL ANALYSIS OF THERMAL RADIATION FROM NEUTRON STARS Annual Status Report No. 2, 1 Apr. 1993 - 31 Mar. 1994
James H. Applegate Jan. 1994 37 p
(Grant NAGw-3075)
(NASA-CR-194808; NAS 1.26:194808; CAL-2151) Avail: CASI HC A03/MF A01

The unambiguous detection of thermal radiation from the surface of a cooling neutron star was one of the most anxiously awaited results in neutron star physics. This particular Holy Grail was found by Halpern and Holt, who used ROSAT to detect pulsed X-rays from the gamma-ray source Geminga and demonstrate that it was a neutron star, probably a radio pulsar beamed away from us. At an age of approximately 3.4 x 10(exp 5) years, Geminga is in the photon cooling era. Its surface temperature of 5.2 x 10(exp 5) K can be explained within the contexts of both the slow and fast cooling scenarios. In the slow cooling scenario, the surface temperature is too high unless the specific heat of the interior is reduced by extensive baryon pairing. In the fast cooling scenario, the surface temperature will be much too low unless the fast neutrino cooling is shut off by baryon pairing. Two other pulsars, PSR 0656+14 and PSR 1055-52, have also been detected in thermal X-rays by ROSAT. They are also in the photon cooling era. All of this research's neutron star cooling models to date have used the unmagnetized effective temperature-interior temperature relation for the outer boundary condition. Models are being improved by using published magnetic envelope calculations and assumed geometried for the surface magnetic field to determine local interior temperature-emitted flux relations for the surface of the star.

THE X RAY HALO OF CEN X-3 Final Report, 24 Jun. 1992 - 23 Jul. 1993
Richard C. Catura 23 Jul. 1993 14 p
(Contract NAS5-31855)
(NASA-CR-189309; NAS 1.26:189309) Avail: CASI HC A03/MF A01

The objective of this research was to study the halo surrounding the ROSAT image of Cen X-3. The halo was formed by the scattering of x rays by interstellar dust grains. An X Ray Halo was observed and that comprised 11.5 percent of the total x rays detected in the central unscattered image. A void at the center of the halo, that was expected to form during eclipse, was not observed. It is likely the void is filled by x rays scattered from cirum-source matter, local to Cen X-3, during eclipse of the x ray source. Author (revised)

THE DISTRIBUTION OF DARK MATTER IN THE A2256 CLUSTER
J. Patrick Henry (Hawaii Univ., Honolulu.), Ulrich G. Briel, and Paul E. J. Nulsen (Wollongong Univ., Australia.) Jan. 1993 11 p Submitted for publication
(Grants NAG5-1789; NATO-CRG-910415)
(NASA-CR-194699; NAS 1.26:194699; MPE-Preprint-242; ETN-93-94922)
Copyright Avail: CASI HC A03/MF A01

Using spatially resolved X-ray spectroscopy, it was determined that the X-ray emitting gas in the rich cluster A2256 is nearly isothermal to a radius of at least 0.76/h Mpc, or about three core radii. These data can be used to measure the distribution of the dark matter in the cluster. It was found that the total mass interior to 0.76/h Mpc and 1.5/h Mpc is (0.5 +/- 0.1 and 1.0 +/- 0.5) x 10(exp 15)/h of the solar mass respectively where the errors encompass the full range allowed by all models used. Thus, the mass appropriate to the region where spectral information was obtained is well determined, but the uncertainties become large upon extrapolating beyond that region. It is shown that the galaxy orbits are midly anisotropic which may cause the beta discrepancy in this cluster.

DUST CONTENT OF A HYDROGEN RICH, LOW SURFACE BRIGHTNESS GALAXY AND THE LUMINOSITY HISTORY OF 3C273 Annual Status Report, 1 Sep. 1992 - 31 Aug. 1993

Thomas T. Hamilton Dec. 1993 5 p

(Grant NAG5-2079)

(NASA-CR-194705; NAS 1.26:194705; CAL-2149) Avail: CASI HC A01/MF A01

This project consists of a 30,000 second PSPC observation of the Giovanelli-Haynes Cloud in an attempt to detect light emitted by 3C273 which has been reflected by the cloud, and incidentally search the cloud for other sources of X-ray emission. The observation was carried out by ROSAT on Dec. 25, 1992 and the data was received by the P.I. in late March of 1993. We have examined the data and determined that the observation's background level, astrometry, etc. are acceptable. We have also detected diffuse emission from the direction of the Giovanelli-Haynes Cloud. Determination of the origin of this emission, by examining its morphology in relation to that of the radio map and the object's geometric relation with 3C273, requires software implementation of specialized algorithms. However, the most dramatic observation in the field is a potentially new population of discrete soft X-ray sources associated with dwarf galaxies. Derived from text

VVNRS: VARIABLE PHENOMENA IN VV CEPHEI Final Report, 1 Dec. 1991 - 30 Nov. 1993

Robert E. Stencel 1993 5 p

(Grant NAG5-1832)

(NASA-CR-194731; NAS 1.26:194731) Avail: CASI HC A01/MF A01

The current research project (VVNRS) involves VV Cephei, which is a binary system in which a 20 solar mass main sequence star orbits within the extended atmosphere of the 40 solar mass M-type supergiant primary. Although the period of the system is 20.3 years, the components are close enough for a stream of matter from the primary to form an accretion disk around the hot secondary. We had previously completed an ADP-sponsored study of twelve years of archival spectra of this system and were surprised to find intermittent changes in the line profiles of the chromosphere-like absorption spectrum. This we think may be related to the accretion process. The previously existing spectra were not closely spaced enough in time to clearly delineate the nature of these changes. Therefore, we proposed and were granted eleven half-shifts to obtain closely spaced IUE spectra during IUE's 14th year of operations (1991/1992). Derived from text

A HIGH RESOLUTION LIQUID XENON IMAGING TELESCOPE FOR 0.3-10 MeV GAMMA RAY ASTROPHYSICS: CONSTRUCTION AND INITIAL BALLOON FLIGHTS Annual Status Report, 1 Jan. 1993 - 31 Dec. 1993

Elena Aprile 31 Dec. 1993 72 p

(Grant NAGw-2013)

(NASA-CR-194709; NAS 1.26:194709; CAL-2150) Avail: CASI HC A04/MF A01

The results achieved with a 3.5 liter liquid xenon time projection chamber (LXe-TPC) prototype during the first year include: the efficiency of detecting the primary scintillation light for event triggering has been measured to be higher than 85%; the charge response has been measured to be stable to within 0.1% for a period of time of about 30 hours; the electron lifetime has been measured to be in excess of 1.3 ms; the energy resolution has been measured to be consistent with previous results obtained with small volume chambers; X-Y gamma ray imaging has been demonstrated with a nondestructive orthogonal wires readout; Monte Carlo simulation results on detection efficiency, expected background count rate at balloon altitude, background reduction algorithms, telescope response to point-like and diffuse sources, and polarization sensitivity calculations; and work on a 10 liter LXe-TPC prototype and gas purification/recovery system. For individual title, see N94-22282.

THE POLARIZATION SENSITIVITY OF THE LIQUID XENON IMAGING TELESCOPE

Elena Aprile, A. Bolotnikov, D. Chen, and R. Mukherjee *In its* A High Resolution Liquid Xenon Imaging Telescope for 0.3-10 MeV Gamma Ray Astrophysics: Construction and Initial Balloon Flights 31 Dec. 1993 18 p Presented at the INTEGRAL Workshop, Les Diableret, Switzerland, 2-5 Feb. 1993 Submitted for publication (For primary document see N94-22281 05-89)

Avail: CASI HC A03/MF A01

The properties and the expected performance of a liquid xenon (LXe) gamma ray imaging telescope, optimized for the MeV energy region, are presented. The unique potential of this telescope as a Compton polarimeter is particularly emphasized. Based on Monte Carlo simulations we show that the modulation factor is as high as 40 percent at 1 MeV with a detection efficiency close to 20 percent. These figures of merit combined with the excellent background suppression capability of the three dimensional position sensitive LXe detector yield sensitivity at the three sigma level to polarization fractions as small as a few percent for strong sources, even in a balloon flight. SURFACE PHOTOMETRY OF THE SHELL GALAXY NGC 2865 M.S. Thesis

David Lee Wing Jul. 1990 111 p

(ISBN-0-315-60441-7; CTN-94-60881) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Independently calibrated charge coupled device surface photometry data were derived from 12 images of the shell galaxy NGC 2865 in the B, V, and R passbands. Short exposures were used to permit accurate sky subtraction. Mean isophotes were derived for each passband over the 3-60 second radial distance range. The isophotes are presented in the form of their best-fit ellipse parameters. The parameters for the best-fit de Vaucouleurs surface brightness law were determined for the mean profile in each passband, and deviations of the actual surface brightness profile from the r to the 1/4 power law are discussed in terms of the galaxy's shell structure. From the best-fit ellipse parameters, the amplitudes of the cosine(4 theta) component of the isophotes could be measured. It was found that they do not show the boxiness often observed in a galaxy which had experienced a recent merger. On the contrary, a peak amplitude of about +1 percent (2 sigma) over the 25-40 second interval suggests only the presence of a weak disk. If the disk is real it indicates NGC 2865 is an S0 galaxy. Both (B-V) and (B-R) color gradients were measured and show the galaxy becomes bluer with increasing radius. This may be explained in terms of a radial metallicity gradient in the sense that the metallicity decreases by about a factor of two per decade increase in distance. Author (CISTI)

AUTOMATED INVESTIGATION OF QUASARS AT A GALACTIC LATITUDE OF -45 DEG M.S. Thesis [RECHERCHE AUTOMATISEE DE QUASARS A UNE LATITUDE GALACTIQUE DE -45 DEG]

Steve Levesque Sep. 1989 210 p In FRENCH

(ISBN-0-315-57576-X; CTN-94-60882) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Within the framework of a long-term study of the large-scale structure of the universe, a study was conducted to compare the properties of homogeneity and isotropy for the distribution of quasars in the universe. Since examination of the entire sky was not possible, certain representative fields were chosen for comparison. Each field was surveyed with the aid of photographic plates to obtain the number of quasars per unit of surface and per unit of distance. Since the data obey a Poisson distribution, it is necessary to analyze a large number of plates to obtain significant information. The GRENS project analyzed 40 fields throughout the sky, and the present thesis undertakes the comparison of the characteristics of three photographic plates from field F at a galactic latitude of -45 deg. These plates are digitized and treated by various software in the GRENS unit, and data obtained on quasar distribution are then compared to those

in other fields using standard statistical tests. The GRENS software used to process the photographic images, correct spectral data, and select candidates for identification as quasars is described. Results of data processing and comparison of the F1, F2, and F3 fields are presented. The results have not allowed detecting any anisotropy in the candidate quasars. CISTI

RESTORATION OF HST IMAGES WITH MISSING DATA Abstract Only
Hans-Martin Adorf *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 8 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Missing data are a fairly common problem when restoring Hubble Space Telescope observations of extended sources. On Wide Field and Planetary Camera images cosmic ray hits and CCD hot spots are the prevalent causes of data losses, whereas on Faint Object Camera images data are lossed due to reseaux marks, blemishes, areas of saturation and the omnipresent frame edges. This contribution discusses a technique for 'filling in' missing data by statistical inference using information from the surrounding pixels. The major gain consists in minimizing adverse spill-over effects to the restoration in areas neighboring those where data are missing. When the mask delineating the support of 'missing data' is made dynamic, cosmic ray hits, etc. can be detected on the fly during restoration. Author

The compute performance, storage capability, degree of networking, and usability of modern computer hardware have enormously progressed in the past decade. These hardware advances are not paralleled by an equivalent increase in software productivity. Among astronomers the need is gradually perceived to discuss questions such as whether we are prepared to meet the pending challenge of vector and massively parallel computers. Therefore, a moderated, time-limited and access-restricted, wide-area network discussion forum is proposed for having a first, broad-minded go at the question of whether our current software efforts are heading in the right direction. The main topics, goals, means, and form of the proposed discussion process are presented. Author

Low-cost vector processing (VP) is within reach of everyone seriously engaged in scientific computing. The advent of affordable add-on VP-boards for standard workstations complemented by mathematical/statistical libraries is beginning to impact compute-intensive tasks such as image processing. A case in point in the restoration of distorted images from the Hubble Space Telescope. A low-cost implementation is presented of the standard Tarasko-Richardson-Lucy restoration algorithm on an Intel i860-based VP-board which is seamlessly interfaced to a commercial, interactive image processing system. First experience is reported (including some benchmarks for standalone FFT's) and some conclusions are drawn. Author

The scientific throughput of a particular observing facility has been demonstrated to be multiplied with the operation of a data archive and its corresponding retrieval system. A requisite to achieve such an exploitation is a well structured observations catalog, i.e. a catalog that includes all information necessary to reduce and analyze the data even many years after its acquisition. At the same time, an information system is required that allow users to browse through the catalog at different levels of detail, adapting the amount of information presented to the actual needs of the user. Archiving data acquired with ground-based telescopes is particularly difficult because of the relative short life-time of instruments and detectors in comparison to the expected life-time of the archive. This feature differentiates ground-based originated archives radically from its spaceborne counterparts. The organization of the observations catalog becomes highly dependent on the capability of the archive to deal with new instrumental configurations. We introduce in this paper, the concept of a catalog database as opposed to the static catalog design currently in use in many archiving facilities, as a method to deal with this problem. We also present a brief review of activities currently in progress in this area. Author

MULTIFREQUENCY DATA ANALYSIS SOFTWARE ON STARLINK Abstract Only c61
P. M. Allan *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 12 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Although the STARLINK project was set up to provide image processing facilities to UK astronomers, it has grown over the last 12 years to the extent that it now provides most of the data analysis facilities for UK astronomers. One aspect of the growth of the STARLINK network is that it now has to cater for astronomers working in a diverse range of wavelengths. Since a given individual may be working with data obtained in a variety of wavelengths, it is most convenient if the data can be stored in a common format and the programs that analyze the data have a similar 'look and feel'. What is known as 'STARLINK software' is obtained from many sources: STARLINK funded programmers; astronomers; foreign projects such as AIPS; generally available shareware; and commercial sources when this proves cost effective. This means that the ideal situation of a completely integrated system cannot be realized in practice. Nevertheless, many of the major packages written by STARLINK application programmers and by astronomers do use a common data format, based on the Hierarchical Data System, so that interchange of data between packages designed separately from each other is simply a matter of using the same file names. For example, as astronomer might use KAPPA to read some optical spectra off a FITS tape, then use CCDPACK to debias and flat field the data (it is easy to set up an overnight batch job to do this if there is a lot of data), then use KAPPA to have a quick look at the data and then use Figaro to reduce the spectra. It is useful to divide data analysis packages into wavelength specific packages, or even instrument specific packages, and general purpose ones. Once the instrumental signature has been removed from some data, any appropriate general purpose package can be used to analyze te data. For example, the ASTERIX package deals with x-ray data reduction, but after dealing with all of the x-ray specific processing, an astronomer may well want to find the brightness of objects in a given frame. Since ASTERIX uses the standard STARLINK data format, the astronomer can use PHOTOM or DAOPHOT 2 to measure the brightness of the objects. Although DAOPHOT was written with optical astronomy in mind, it is useful for analyzing data from several wavelengths. The ability of DAOPHOT 2 to handle non-standard point spread functions can be especially useful in many areas of astronomy. Author

The Macho Project has undertaken a 5 year effort to search for dark matter in the halo of the Galaxy by scanning the Magellanic Clouds for micro-lensing events. Each evening's raw image data will be reduced in real-time into the observed stars' photometric measurements. The actual search for micro-lensing events will be a post-processing operation. The theoretical prediction of the rate of such events necessitates the collection of a large number of repeated exposures. The project designed camera subsystem delivers 64 Mbytes per exposure with exposures typically occurring every 500 seconds. An ideal evening's observing will provide 6 Gbytes of raw image data and 40 Mbytes of reduced photometric measurements. Recognizing the difficulty of digging out from a snowballing cascade of raw data, the project requires the real-time reduction of each evening's data. The software team's implementation strategy centered on this non-negotiable mandate. Accepting the reality that 2 full time people needed to implement the core real-time control and data management system within 6 months, off-the-shelf vendor components were explored to provide quick solutions to the classic needs for file management, data management, and process control. Where vendor solutions were lacking, state-of-the-art models were used for hand tailored subsystems. In particular, petri nets manage process control, memory mapped bulletin boards provide interprocess communication between the multi-tasked processes, and C++ class libraries provide memory mapped, disk resident databases. The differences between the implementation strategy and the final implementation reality are presented. The necessity of validating vendor product claims are explored. Both the successful and hindsight decisions enabling the collection and processing of the nightly data barrage are reviewed. Author

We present here the results based on analysis of broad band optical images of radio loud and radio quiet galaxies selected from a set of x-ray galaxies. Data reduction techniques, and surface photometry using the IRAF data reduction package are described. The radial surface brightness profile of each galaxy is obtained. The disc, bulge, and nucleus of the galaxy are modeled based on the estimated brightness profile. The model of the galaxy is constructed, which is subtracted from the observed image to enhance the small scale features in the galaxy. Color maps of the galaxy are obtained and compared with those of normal galaxies. The optical properties of the galaxy are compared with its x-ray and radio properties. Author

THE COOL-STAR SPECTRAL CATALOG: A UNIFORM COLLECTION OF IUE SWP-LOs Abstract Only **c82**
T. Ayres (Colorado Univ., Boulder.), D. Lenz (Colorado Univ., Boulder.), R. Burton (Colorado Univ., Boulder.), and J. Bennett *In its* Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 15 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Over the past decade and a half of its operations, the International Ultraviolet Explorer has recorded low-dispersion spectrograms in the 1150-2000 A interval of more than 800 stars of late spectral type (F-M). The sub-2000 A region contains a number of emission lines that are key diagnostics of physical conditions in the high-excitation chromospheres and subcoronal 'transition zones' of such stars. Many of the sources have been observed a number of times, and the available collection of SWP-LO exposures in the IUE Archives exceeds 4,000. With support from the Astrophysics Data Program, we have assembled the archival material into a catalog of IUE far-UV fluxes of late-type stars. In order to ensure uniform processing of the spectra, we: (1) photometrically corrected the raw vidicon images with a custom version of the 1985 SWP ITF; (2) identified and eliminated, sharp cosmic-ray 'hits' by means of a spatial filter; (3) extracted the spectral traces with the 'optimal' (weighted-slit) strategy; and (4) calibrated them against a well-characterized reference source, the DA white dwarf G191-B2B. Our approach is similar to that adopted by the IUE Project for its 'Final Archive', but our implementation is specialized to the case of chromospheric emission-line sources. We measured the resulting SWP-LO spectra using a semi-autonomous algorithm that establishes a smooth continuum by numerical filtering, and then fits the significant emissions (or absorptions) by means of a constrained Bevington-type multiple-Gaussian procedure. The algorithm assigns errors to the fitted fluxes - or upper limits in the absence of a significant detection - according to a model based on careful measurements of the noise properties of the IUE's intensified SEC cameras. Here, we describe the 'visualization' strategies we adopted to ensure human-review of the semi-autonomous processing and measuring algorithms; the derivation of the noise model and the assignment of errors; and the structure of the final catalog as delivered to the Astrophysics Data System. AN OBJECT-ORIENTED DATA REDUCTION SYSTEM IN FORTRAN Abstract Only **c82**
J. Bailey *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 16 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

A data reduction system for the AAO two-degree field project is being developed using an object-oriented approach. Rather than use an object-oriented language (such as C++) the system is written in Fortran and makes extensive use of existing subroutine libraries provided by the UK Starlink project. Objects are created using the extensible N-dimensional Data Format (NDF) which itself is based on the Hierarchical Data System (HDS). The software consists of a class library, with each class corresponding to a Fortran subroutine with a standard calling sequence. The methods of the classes provide operations on NDF objects at a similar level of functionality to the applications of conventional data reduction systems. However, because they are provided as callable subroutines, they can be used as building blocks for more specialist applications. The class library is not dependent on a particular software environment thought it can be used effectively in ADAM applications. It can also be used from standalone Fortran programs. It is intended to develop a graphical user interface for use with the class library to form the 2dF data reduction system. Author

A SELF-DEFINING HIERARCHICAL DATA SYSTEM Abstract Only **c82**
J. Bailey *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 17 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The Self-Defining Data System (SDS) is a system which allows the creation of self-defining hierarchical data structures in a form which allows the data to be moved between different machine architectures. Because the structures are self-defining they can be used for communication between independent modules in a distributed system. Unlike disk-based hierarchical data systems such as Starlink's HDS, SDS works entirely in memory and is very fast. Data structures are created and manipulated as internal dynamic structures in memory managed by SDS itself. A structure may then be exported into a caller supplied memory buffer in a defined external format. This structure can be written as a file or sent as a message to another machine. It remains static in structure until it is reimported into SDS. SDS is written in portable C and has been run on a number of different machine architectures. Structures are portable between machines with SDS looking after conversion of byte order, floating point format, and alignment. A Fortran callable version is also available for some machines. Author

MIDAS (Munich Image Data Analysis System) is the image processing system developed at ESO for astronomical data reduction. MIDAS is used for off-line data reduction at ESO and many astronomical institutes all over Europe. In addition to a set of general commands, enabling to process and analyze images, catalogs, graphics and tables, MIDAS includes specialized packages dedicated to astronomical applications or to specific ESO instruments. Several graphical interfaces are available in the MIDAS environment: XHelp provides an interactive help facility, and XLong and XEchelle enable data reduction of long-slip and echelle spectra. GUI builders facilitate the development of interfaces. All ESO interfaces comply to the ESO User Interfaces Common Conventions which secures an identical look and feel for telescope operations, data analysis, and archives.

A STRUCTURED DATA TRANSFER PROTOCOL Abstract Only c82
P. Barrett and A. Rots *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 19 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The transfer of data between different computers and programs can be a major obstacle during data analysis. We present a new data transfer protocol which is based on a simple structure containing a value, an error, and a unit. Each of these members can be arrays or another structure. The ability to nest structures allows for the concept of objects. When using an object-oriented language such as C++, reference can be made to the object name instead of each element explicitly. Prototype code has been written which implements the basic design with enhancements planned for the future.

A NEURAL NETWORK PROTOTYPING PACKAGE WITHIN IRAF Abstract Only c63
D. Bazell and I. Bankman (Johns Hopkins Univ., Baltimore, MD.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 20 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

We outline our plans for incorporating a Neural Network Prototyping Package into the IRAF environment. The package we are developing will allow the user to choose between different types of networks and to specify the details of the particular architecture chosen. Neural networks consist of a highly interconnected set of simple processing units. The strengths of the connections between units are determined by weights which are adaptively set as the network 'learns'. In some cases, learning can be a separate phase of the user cycle of the network while in other cases the network learns continuously. Neural networks have been found to be very useful in pattern recognition and image processing applications. They can form very general 'decision boundaries' to differentiate between objects in pattern space and they can be used for associative recall of patterns based on partial cures and for adaptive filtering. We discuss the different architectures we plan to use and give examples of what they can do.

DATABASE ACTIVITY IN THE ITALIAN ASTRONET: DIRA 2 Abstract Only c82
L. Benacchio and M. Nanni (Bologna Univ., Italy.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 21 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The development and utilization of informational archives and databases started, in the Italian Astronet Project, in the middle of 1983. In that year, a small group of astronomers and some more technical people met together in an Astronet working group, with a common, painful experience in managing astronomical catalogues and archives with computers. Nowadays, some years later, some software packages and the contents of both, a relative general database and several local databases represent the work and the effort of the group. The systems have been conceived and developed keeping in mind the original goal of the group: to allow the single atronomer to make a free use of original data. The main package (DIRA) was rewritten, after some years of use, to fully take advantage of the several suggestions of the astronomer that used it and gathered experiences in the astronomical catalog's management. A more technical goal was to install the whole system, born and developed in the vms environment, on unix and unix-like systems. This new version, DIRA2, has a new user interface, a query language with SQL style commands supporting numerical and character functions also and a set of commands to create new catalogues from existing data. The graphics commands are also more powerful with respect to the previous version. DIRA (and DIRA2 of course) philosophy and design are very simple and proved to be very appreciated by astronomers, namely, to normalize and homogenize, at minimum, astronomical catalogues, to collect satisfactory astronomical documentation on their contents and, finally, to allow an astronomical approach to the dialogue with the database. DIRA2 is currently used in most Italian astronomical institutes to retrieve data from a still growing database of about 140 well documented and controlled astronomical catalogues, for the identification of objects and the preparation of a 'medium size' survey, in astrometry and in the creation of new catalogues.

THE ALEXIS DATA PROCESSING PACKAGE: AN IDL BASED SYSTEM Abstract Only c82
J. J. Bloch, B. W. Smith, and B. C. Edwards *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 22 Sponsored in part by DOE (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The Array of Low Energy X-ray Imaging Sensors (ALEXIS) experiment consists of a mini-satellite containing six wide angle EUV/ultrasoft x-ray telescopes. Its purpose is to map out the sky in three narrow (approximately 5 percent) bandpasses around 66, 71, and 93 eV. The 66 and 71 eV bandpasses are centered on intense Fe emission lines which are characteristic of million degree plasmas such as the one thought to produce the soft x-ray background. The 93 eV bandpass is not near any strong emission lines and is more sensitive to continuum sources. The mission will be launched on the Pegasus Air Launched Vehicle in the second half of 1992 into a 400-nautical-mile, high inclination orbit and will be controlled entirely from a small ground station located at Los Alamos. The project is a collaborative effort between Los Alamos National Laboratory, Sandia National Laboratory, and the University of California-Berkeley Space Sciences Laboratory. The six telescopes are arranged in three pairs. As the satellite spins twice a minute they scan the entire anti-solar hemisphere. Each f/1 telescope consists of a spherical, multilayer-coated mirror with a curved, microchannel plate detector located at the prime focus. The multilayer coatings determine the bandpasses of the telescopes. The field of view of each telescope is 30 degrees with a spatial resolution of 0.5 degree, limited by spherical aberration. The data processing requirements for ALEXIS are large. Each event is one of the six telescopes is telemetered to the ground with its time of arrival and position on the detector. This information must be folded with the aspect solution for the satellite to reconstruct the direction on the sky from which the photon came. Because of the way the six telescopes scan the sky, the effective exposure calculation is also very computationally intensive. ALEXIS may generate up to 100 megabytes of raw data per day, which are converted into a gigabyte per day of processed data. While the processing job for ALEXIS is sizable, the programming staff is small. To maximize programming efficiency, and to make the best use of tools available in the public domain, we chose IDL as our software development platform. IDL was used from the start of instrument development through flight. We use IDL as a top-level executive for the processing tasks (replacing Unix shell scripts), as a device independent graphics engine, as a database manager, and as a final data manipulator. IDL routines spawn special purpose C programs to perform detailed telemetry deconvolution and other specialized functions. We discuss the use of IDL and C within the processing and archiving strategy for the ALEXIS data anlaysis system as implemented on a SPARCstation platform. We also

show results from our End-to-End software simulation capability as processed by our analysis codes. Author

Unlike traditional 'serial' processing computers in which one central processing unit performs one instruction at a time, parallel processing computers contain several processing units, thereby, performing several instructions at once. Many of today's fastest supercomputers achieve their speed by employing thousands of processing elements working in parallel. Few institutions can afford these state-of-the-art parallel processors, but many already have the makings of a modest parallel processing system. Workstations on existing high-speed networks can be harnessed as nodes in a parallel processing environment, bringing the benefits of parallel processing to many. While such a system can not rival the industry's latest machines, many common tasks can be accelerated greatly by spreading the processing burden and exploiting idle network resources. We study several aspects of this approach, from algorithms to select nodes to speed gains in specific tasks. With ever-increasing volumes of astronomical data, it becomes all the more necessary to utilize our computing resources fully. Author

We describe the X-ray Data Acquisition and Control System (XDACS) used together with the X-ray Detection System (XDS) to characterize the x-ray image during testing of the AXAF P1/H1 mirror pair at the MSFC X-ray Calibration Facility. A variety of x-ray data were acquired, analyzed, and archived during the testing including: mirror alignment, encircled energy, effective area, point spread function, system housekeeping, and proportional counter window uniformity data. The system architecture will be presented with emphasis placed on key features that include a layered UNIX tool approach, dedicated subsystem controllers, real-time X-window displays, flexibility in combining tools, network connectivity, and system extensibility. The VETA test data archive are also described. Author

A MULTIRESOLUTION WAVELET REPRESENTATION IN TWO OR MORE DIMENSIONS Abstract Only **c61**
B. C. Bromley *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 25 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

In the multiresolution approximation, a signal is examined on a hierarchy of resolution scales by projection onto sets of smoothing functions. Wavelets are used to carry the detail information connecting adjacent sets in the resolution hierarchy. An algorithm has been implemented to perform a multiresolution decomposition in n greater than or equal to 2 dimensions based on wavelets generated from products of 1-D wavelets and smoothing functions. The functions are chosen so that an n-D wavelet may be associated with a single resolution scale and orientation. The algorithm enables complete reconstruction of a high resolution signal from decomposition coefficients. The signal may be oversampled to accommodate non-orthogonal wavelet systems, or to provide approximate translational invariance in the decomposition arrays. Author

EXPERIMENTS WITH RECURSIVE ESTIMATION IN ASTRONOMICAL IMAGE PROCESSING Abstract Only **c82**
I. Busko *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 26 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Recursive estimation concepts were applied to image enhancement problems since the 70's. However, very few applications in the particular area of astronomical image processing are known. These concepts were derived, for 2-dimensional images, from the well-known theory of Kalman filtering in one dimension. The historic reasons for application of these techniques to digital images are related to the images' scanned nature, in which the temporal output of a scanner device can be processed on-line by techniques borrowed directly from 1-dimensional recursive signal analysis. However, recursive estimation has particular properties that make it attractive even in modern days, when big computer memories make the full scanned image available to the processor at any given time. One particularly important aspect is the ability of recursive techniques to deal with non-stationary phenomena, that is, phenomena which have their statistical properties variable in time (or position in a 2-D image). Many image processing methods make underlying stationary assumptions either for the stochastic field being imaged, for the imaging system properties, or both. They will underperform, or even fail, when applied to images that deviate significantly from stationarity. Recursive methods, on the contrary, make it feasible to perform adaptive processing, that is, to process the image by a processor with properties tuned to the image's local statistical properties. Recursive estimation can be used to build estimates of images degraded by such phenomena as noise and blur. We show examples of recursive adaptive processing of astronomical images, using several local statistical properties to drive the adaptive processor, as average signal intensity, signal-to-noise and autocorrelation function. Software was developed under IRAF, and as such will be made available to interested users. Author

EXTRACTING GALACTIC STRUCTURE PARAMETERS FROM MULTIVARIATED DENSITY ESTIMATION Abstract Only **c65**
B. Chen, M. Creze, A. Robin (Observatoire de Besancon, France.), and O. Bienayme (Observatoire de Besancon, France.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 27 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Multivariate statistical analysis, including includes cluster analysis (unsupervised classification), discriminant analysis (supervised classification) and principle component analysis (dimensionlity reduction method), and nonparameter density estimation have been successfully used to search for meaningful associations in the 5-dimensional space of observables between observed points and the sets of simulated points generated from a synthetic approach of galaxy modelling. These methodologies can be applied as the new tools to obtain information about hidden structure otherwise unrecognizable, and place important constraints on the space distribution of various stellar populations in the Milky Way. In this paper, we concentrate on illustrating how to use nonparameter density estimation to substitute for the true densities in both of the simulating sample and real sample in the five-dimensional space. In order to fit model predicted densities to reality, we derive a set of equations which include n lines (where n is the total number of observed points) and m (where m: the numbers of predefined groups) unknown parameters. A least-square estimation will allow us to determine the density law of different groups and components in the Galaxy. The output from our software, which can be used in many research fields, will also give out the systematic error between the model and the observation by a Bayes rule. Author

THE EUVE PROPOSAL DATABASE AND SCHEDULING SYSTEM Abstract Only **c82**
C. Christian, E. Olson, P. Jelinsky, and M. Samuel *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 28 (For primary document see N94-22438

05-89)
Avail: CASI HC A01/MF A02

The proposal database and scheduling system for the Extreme Ultraviolet Explorer will be described. The proposal database has been implemented to take input for approved observations selected by the EUVE Peer Review Panel and output target information suitable for the scheduling system to digest. The scheduling system is a hybrid of the SPIKE program and EUVE software which checks spacecraft constraints, produces a proposed schedule and selects spacecraft orientations with optimal configurations for acquiring star trackers, etc. This system has been used to schedule the In Orbit Calibration activities that took place this summer, following the EUVE launch in early June 1992. The implemented strategy has implications for the selection of approved targets, which have impacted the Peer Review process. In addition, it will be discussed how the proposal database, founded on Sybase, controls the processing of EUVE Guest Observer data.

THE KECK KEYWORD LAYER Abstract Only **c61**
A. R. Conrad and W. F. Lupton *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 29 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Each Keck instrument presents a consistent software view to the user interface programmer. The view consists of a small library of functions, which are identical for all instruments, and a large set of keywords, that vary from instrument to instrument. All knowledge of the underlying task structure is hidden from the application programmer by the keyword layer. Image capture software uses the same function library to collect data for the image header. Because the image capture software and the instrument control software are built on top of the same keyword layer, a given observation can be 'replayed' by extracting keyword-value pairs from the image header and passing them back to the control system. The keyword layer features non-blocking as well as blocking I/O. A non-blocking keyword write operation (such as setting a filter position) specifies a callback to be invoked when the operation is complete. A non-blocking keyword read operation specifies a callback to be invoked whenever the keyword changes state. The keyword-callback style meshes well with the widget-callback style commonly used in X window programs. The first keyword library was built for the two Keck optical instruments. More recently, keyword libraries have been developed for the infrared instruments and for telescope control. Although the underlying mechanisms used for inter-process communication by each of these systems vary widely (Lick MUSIC, Sun RPC, and direct socket I/O, respectively), a basic user interface has been written that can be used with any of these systems. Since the keyword libraries are bound to user interface programs dynamically at run time, only a single set of user interface executables is needed. For example, the same program, 'xshow', can be used to display continuously the telescope's position, the time left in an instrument's exposure, or both values simultaneously. Less generic tools that operate on specific keywords, for example an X display that controls optical instrument exposures, have also been written using the keyword layer.

PROS: AN IRAF BASED SYSTEM FOR ANALYSIS OF X RAY DATA Abstract Only **c61**
M. A. Conroy, J. DePonte, J. F. Moran, J. S. Orszak, W. P. Roberts, and D. Schmidt *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 30 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

PROS is an IRAF based software package for the reduction and analysis of x-ray data. The use of a standard, portable, integrated environment provides for both multi-frequency and multi-mission analysis. The analysis of x-ray data differs from optical analysis due to the nature of the x-ray data and its acquisition during constantly varying conditions. The scarcity of data, the low signal-to-noise ratio and the large gaps in exposure time make data screening and masking an important part of the analysis. PROS was developed to support the analysis of data from the ROSAT and Einstein missions but many of the tasks have been used on data from other missions. IRAF/PROS provides a complete end-to-end system for x-ray data analysis: (1) a set of tools for importing and exporting data via FITS format -- in particular, IRAF provides a specialized event-list format, QPOE, that is compatible with its IMAGE (2-D array) format; (2) a powerful set of IRAF system capabilities for both temporal and spatial event filtering; (3) full set of imaging and graphics tasks; (4) specialized packages for scientific analysis such as spatial, spectral and timing analysis -- these consist of both general and mission specific tasks; and (5) complete system support including ftp and magnetic tape releases, electronic and conventional mail hotline support, electronic mail distribution of solutions to frequently asked questions and current known bugs. We will discuss the philosophy, architecture and development environment used by PROS to generate a portable, multimission software environment. PROS is available on all platforms that support IRAF, including Sun/Unix, VAX/VMS, HP, and Decstations. It is available on request at no charge.

ROSAT IMPLEMENTATION OF A PROPOSED MULTI-MISSION X RAY DATA FORMAT Abstract Only **c82**
M. Corcoran, W. Pence, R. White, and M. Conroy (Smithsonian Astrophysical Observatory, Cambridge, MA.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 31 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Until recently little effort has been made to ensure that data from X-ray telescopes are delivered in a format that reflects the common characteristics that most X-ray datasets share. Instrument-specific data-product design hampers the comparison of X-ray measurements made by different detectors and should be avoided whenever possible. The ROSAT project and the High Energy Astrophysics Science Archive Research Center (HEASARC) have defined a set of X-ray data products ('rationalized files') for ROSAT data that can be used for distribution and archiving of data from other X-ray missions. This set of 'rationalized files' has been defined to isolate instrument-independent and instrument-specific quantities using standards FITS constructs to ensure portability. We discuss the usage of the 'rationalized files' by ROSAT for data distribution and archiving, with particular emphasis on discrimination between instrument-independent and instrument-specific quantities, and discuss application of this format to data from other X-ray missions.

The AIPS system that has served the needs of the radio astronomical community remarkably well during the last 15 years is showing signs of age and is being replaced by a more modern system, AIPS++. As the name implies, AIPS++ will be developed in a object oriented fashion and will use C++ as its main programming language. The work is being done by a consortium of seven organizations, with coordinated activities worldwide. After a review of the history of the project to this date from management, astronomical and technical viewpoints, and the current state of the project, the paper concentrates on the tradeoffs implied by the choice of implementation style and the lessons we have learned, good and bad.

PHOTCAL: THE IRAF PHOTOMETRIC CALIBRATION PACKAGE Abstract Only **c61**
L. E. Davis and P. Gigoux (Cerro Tololo Inter-American Observatory, La Serena, Chile.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 34 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The IRAF photmetric calibration package PHOTCAL is discussed. PHOTCAL is a set of tasks designed to derive the transformation from the instrumental photometric system to the standard photometric system, and apply the transformation to the observations. The PHOTCAL package contains tasks for: (1) creating and/or editing standard star catalogs and observations catalogs, (2) creating, checking and editing the configuration file which specifies the format of the standard star and observations catalogs and the form of the transformation equations, (3) solving the transformation equations interactively or non-iteractively using non-linear least squares fitting routines, and (4) applying the transformation to the observations. PHOTCAL standard star and observations catalogs are simple text files, whose columns are delimited by whitespace, and whose first column contains the star names. This format makes it relatively easy to interface the output of non-IRAF photometry programs as well as the output of the IRAF APPHOT and DAOPHOT photometry packages to PHOTCAL. PHOTCAL maintains a standard star catalog directory for the convenience of the user, but users can easily create their own standard star catalogs and/or define their own standard star catalog directory. Separate observations files produced by APPHOT, DAOPHOT or a user program containing data for stellar fields taken through different filters, can be combined into observations catalogs using one of the PHOTCAL preprocessor tasks. The input configuration file required by PHOTCAL is a text file, consisting of a series of instructions written by the user in a mini-language understood by the PHOTCAL parser. These instructions: (1) assign names to the input data columns in the standard star and observations catalogs, (2) assign names and initial values to the parameters to be fit, (3) define and describe how to solve the transformation equations. The mini-language approach permits great flexibility in the format of the input catalogs and the form of the transformation equations. Author

DETECTION OF X RAY SOURCES IN PROS Abstract Only
J. DePonte and F. A. Primini *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 35 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The problem of detecting discrete sources in x-ray images has much in common with the problem of automatic source detection at other wavelengths. In all cases, one searches for positive brightness enhancements exceeding a certain threshold, which appear consistent with what one expects for a point source, in the presence of a (possibly) spatially variable background. Multidimensional point spread functions (e.g., dependent on detector position and photon energy) are also common. At the same time, the problem in x-ray astronomy has some unique aspects. For example, for typical x-ray exposures in current or recent observatories, the number of available pixels far exceeds the number of actual x-ray events, so Poisson, rather than Gaussian statistics apply. Further, extended cosmic x-ray sources are common, and one often desires to detect point sources in the vicinity or even within bright, diffuse x-ray emission. Finally, support structures in x-ray detectors often cast sharp shadows in x-ray images making it necessary to detect sources in a region of rapidly varying exposure. We have developed a source detection package within the IRAF/PROS environment which attempts to deal with some of the problems of x-ray source detection. We have patterned our package after the successful Einstein Observatory x-ray source detection programs. However, we have attempted to improve the flexibility and accessibility of the functions and to provide a graphical front-end for the user. Our philosophy has been to use standard IRAF tasks whenever possible for image manipulation and to separate general functions from mission-specific ones. We will report on the current status of the package and discuss future developments, including simulation tasks, to allow the user to assess detection efficiency and source significance, tasks to determine source intensity, and alternative detection algorithms. DEEP NEAR-INFRARED SURVEY OF THE SOUTHERN SKY (DENIS) Abstract Only
E. Deul *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 36 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

DENIS (Deep Near-Infrared Survey of the Southern Sky) will be the first complete census of astronomical sources in the near-infrared spectral range. The challenges of this novel survey are both scientific and technical. Phenomena radiating in the near-infrared range from brown dwarfs to galaxies in the early stages of cosmological evolution, the scientific exploitation of data relevant over such a wide range requires pooling expertise from several of the leading European astronomical centers. The technical challenges of a project which will provide an order of magnitude more sources than given by the IRAS space mission, and which will involve advanced data-handling and image-processing techniques, likewise require pooling of hardware and software resources, as well as of human expertise. The DENIS project team is composed of some 40 scientists, computer specialists, and engineers located in 5 European Community countries (France, Germany, Italy, The Netherlands, and Spain), with important contributions from specialists in Australia, Brazil, Chile, and Hungary. DENIS will survey the entire southern sky in 3 colors, namely in the I band at a wavelength of 0.8 micron, in the 1.25 micron J band, and in the 2.15 micron K' band. The sensitivity limits will be 18th magnitude in the I band, 16th in the J band, and 14.5th in the K' band. The angular resolution achieved will be 1 arcsecond in the I band, and 3.0 arcseconds in the J and K' bands. The European Southern Observatory 1 m telescope on La Silla will be dedicated to survey use during operations expected to last four years, commencing in late 1993. DENIS aims to provide the astronomical community with complete digitized infrared images of the full southern sky and a catalogue of extracted objects, both of the best quality and in readily accessible form. This will be achieved through dedicated software packages and specialized catalogues, and with assistance from the Leiden and Paris Data Analysis Centers. The data will be mailed on DAT tapes from La Silla to the two Data Analysis Centers for further processing. Two centers are necessary because of the shear quantity of data and because of the complementary roles the Centers will develop, each exploiting its own particular expertise. The Leiden Data Analysis Center (LDAC) will extract objects, establish their parameters, and archive them into a source catalogue. The LDAC will collaborate with the Groningen Space Research group that has gained experience in infrared image handling from the IRAS satellite. The Paris Data Analysis Center (PDAC) will be responsible for archiving and preprocessing the raw data to provide a homogeneous set of data suitable for further reduction in both the Leiden and Paris data analysis streams. The PDAC will also extract and archive images for the sources flagged by the LDAC as extended, and create a catalogue of galaxies. In exploiting the DENIS data we foresee the collaboration with other data analysis centers, such as the Observatoire de Lyon where the relevant DENIS catalogue of galaxies can be incorporated into their extragalactic database. The Point Sources and the Small Extended Sources catalogues could be incorporated in the Late Type Star database at Montpellier, and in the SIMBAD database as CDS. At Groningen the IRAS Point Source catalogue and/or image data can be merged with the DENIS catalogues. At Meudon algorithms and software will be developed with main goal assessing the limits reachable for the homogeneity and intrinsic consistency between the ensemble of the images in the data base (flat-fielding, relative positioning of the fields, bootstrapped flux calibration) but also for the data analysis. THE EXTREME ULTRAVIOLET EXPLORER ARCHIVE Abstract Only **c82**
Jeremy J. Drake, Carl Dobson, and Elisha Polomski *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 37 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The Extreme Ultraviolet Explorer (EUVE) satellite was launched successfully at 12:400:00 EDT on June 7, 1992 from Cape Canaveral Air Force Station, Florida. The EUVE science payload consists of three scanning

telescopes carrying out an all-sky survey in the 70-760A spectral region, and a Deep Survey/Spectrometer telescope performing a deep survey in the 70-250A spectral region. This latter instrumentation will subsequently perform Guests Observer (GO) spectroscopic observations of individual targets. The EUVE public archive opened for business on July 17, 1992. The purpose of the archive is the storage and distribution of EUVE data and ancillary documentation, information and software which is in the public domain. As the mission proceeds, the all-sky survey, deep survey and spectroscopic data will become publicly available through a variety of interfaces to an archive system centered around an optical juke box. In this paper, we describe the current and future contents, the architecture, and the development plans for the archive. Author

A DISTRIBUTED CLIENTS/DISTRIBUTED SERVERS MODEL FOR STARCAT Abstract Only **c82**
B. Pirenne, M. A. Albrecht, D. Durand (CADC, British Columbia.), and S. Gaudet (CADC, British Columbia.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 38 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

STARCAT, the Space Telescope ARchive and CATalogue user interface has been along for a number of years already. During this time it has been enhanced and augmented in a number of different fields. This time, we would like to dwell on a new capability allowing geographically distributed user interfaces to connect to geographically distributed data servers. This new concept permits users anywhere on the internet running STARCAT on their local hardware to access e.g., whichever of the 3 existing HST archive sites is available, or get information on the CFHT archive through a transparent connection to the CADC in BC or to get the La Silla weather by connecting to the ESO database in Munich during the same session. Similarly PreView (or quick look) images and spectra will also flow directly to the user from wherever it is available. Moving towards an 'X'-based STARCAT is another goal being pursued: a graphic/image server and a help/doc server are currently being added to it. They should further enhance the user independence and access transparency. Author

The IRAF graphics kernel, psikern, is a true encapsulated PostScript implementation, an improvement over the former SGI-based PostScript output available from IRAF. The psikern kernel implements many more capabilities of gio/gki such as cell arrays (grayscale images), color, filled area patterns and true PostScript fonts. Several of the general-purpose graphics tasks in STSDAS such as igi, sgraph, skymap, and wcslab have been modified to use these capabilities explicitly. Other graphics tasks not enhanced explicitly can also make use of new capabilities such as PostScript font support. We present an overview of psikern and several examples of output created by the enhanced STSDAS tasks. Author

AN IDL-BASED ANALYSIS PACKAGE FOR COBE AND OTHER SKYCUBE-FORMATTED ASTRONOMICAL DATA Abstract Only **c61**
J. A. Ewing, Richard B. Isaacman, and J. M. Gales *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 40 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

UIMAGE is a data analysis package written in IDL for the Cosmic Background Explorer (COBE) project. COBE has extraordinarily stringent accuracy requirements: 1 percent mid-infrared absolute photometry, 0.01 percent submillimeter absolute spectrometry, and 0.0001 percent submillimeter relative photometry. Thus, many of the transformations and image enhancements common to analysis of large data sets must be done with special care. UIMAGE is unusual in this sense in that it performs as many of its operations as possible on the data in its native format and projection, which in the case of COBE is the quadrilateralized sphereical cube ('skycube'). That is, after reprojecting the data, e.g., onto an Aitoff map, the user who performs an operation such as taking a crosscut or extracting data from a pixel is transparently acting upon the skycube data from which the projection was made, thereby preserving the accuracy of the result. Current plans call for formatting external data bases such as CO maps into the skycube format with a high-accuracy transformation, thereby allowing Guest Investigators to use UIMAGE for direct comparison of the COBE maps with those at other wavelengths from other instruments. It is completely menu-driven so that its use requires no knowledge of IDL. Its functionality includes I/O from the COBE archives, FITS files, and IDL save sets as well as standard analysis operations such as smoothing, reprojection, zooming, statistics of areas, spectral analysis, etc. One of UIMAGE's more advanced and attractive features is its terminal independence. Most of the operations (e.g., menu-item selection or pixel selection) that are driven by the mouse on an X-windows terminal are also available using arrow keys and keyboard entry (e.g., pixel coordinates) on VT200 and Tektronix-class terminals. Even limited grey scales of images are available this way. Obviously, image processing is very limited on this type of terminal, but it is nonetheless surprising how much analysis can be done on that medium. Such flexibility has the virtue of expanding the user community to those who must work remotely on non-image terminals, e.g., via modem. Author

VISUALIZING THE UNIVERSE, PART 2 Abstract Only **c90**
Emilio E. Falco, Michael J. Kurtz, and Mark Bajuk (National Center for Supercomputing Applications, Urbana, IL.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 41 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

It is now possible to create animated views of the universe that are realistic, physically relevant, and breathtaking. To demonstrate the point, we describe our efforts to navigate the CfA redshift survey. For our project, we selected several CCD images of spiral and elliptical galaxies, and placed them at their observed positions in redshift space. We demonstrate how, by choreographing aesthetically pleasing trajectories, we are able to develop our own and the viewer's intuition about the large-scale structures found in the CfA redshift survey. We show for instance that three-dimensional motion enhances significantly our perception of voids and sheets in the distribution of galaxies. Such sophistication happily has become possible with the 'coming of age' of observational cosmology, as data have grown to drive the field. Author

C++, OBJECTED-ORIENTED PROGRAMMING, AND ASTRONOMICAL DATA MODELS Abstract Only
A. Farris *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 42 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Contemporary astronomy is characterized by increasingly complex instruments and observational techniques, higher data collection rates, and large data archives, placing severe stress on software analysis systems. The object-oriented paradigm represents a significant new approach to software design and implementation that holds great promise for dealing with this increased complexity. The basic concepts of this approach will be characterized in contrast to more traditional procedure-oriented approaches. The fundamental features of objected-oriented programming will be discussed from a C++ programming language perspective, using examples familiar to astronomers. This discussion will focus on objects, classes and their relevance to the data type system; the principle of information hiding; and the use of inheritance to implement generalization/specialization relationships. Drawing on the object-oriented approach, features of a new database model to support astronomical data analysis will be presented. Author

SPPTOOLS: PROGRAMMING TOOLS FOR THE IRAF SPP LANGUAGE Abstract Only **c61**
M. Fitzpatrick *In* NASA, Washington, Second Annual Conference on

Astronomical Data Analysis Software and Systems. Abstracts 1992 p 43 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

An IRAF package to assist in SPP code development and debugging is described. SPP is the machine-independent programming language used by virtually all IRAF tasks. Tools have been written to aide both novice and advanced SPP programmers with development and debugging by providing tasks to check the code for the number and type of arguments in all calls to IRAF VOS library procedures, list the calling sequences of IRAF tasks, create a database of identifiers for quick access, check for memory which is not freed, and a source code formatter. Debugging is simplified since the programmer is able to get a better understanding of the structure of his/her code, and IRAF library procedure calls (probably the most common source of errors) are automatically checked for correctness. These decades are the first in which we can begin to map the universe. Recent surveys reveal patterns in the distribution of galaxies -- patterns coherent on scales of 150 million light years or more. These patterns contrast with the smoothness of the radiation background measured by the COBE satellite. Together these observations challenge our understanding of the origin of galaxies and large-scale structure in the universe. 'Visualizing the universe' is crucial for exploring the 3-dimensional maps, for analyzing them, for comparing the data with simulations, for designing instruments to make deeper maps with new large telescopes, and for sharing the excitement of discovery with the public. Over the last seven years, the CPU on my desk has increased speed by two orders of magnitude, from around 1 MIP to more than 100 MIPS; more important is that it is about as fast as any uniprocessor of any type available for any price, for compute bound problems. Memory on the system is also about 100 times as big, while disk is only about 10 times as big. Local network and I/O performance have increased greatly, though not quite at the same rate as processor speed. More important, I will argue, is that the CPU's address space is 64 bits, rather than 32 bits, allowing us to rethink some time honored presumptions. The Internet has gone from a few hundred machines to a million, and now have grown to span the entire globe, and wide area networks have now becoming commercial services. 'PC's' are now real computers, bringing what was top of the line computing capability to the masses only a few years behind the leading edge. So even a year or two from now, we can anticipate commonplace desktop machines running at speeds hundreds of MIPS, with main memories in the hundreds of megabytes to a gigabyte, able to draw millions of vectors/second, and all capable of some reasonable 3D graphics. And only a few years later, this will be the $1500 PC. So the 1990's certainly brings: 64 bit processors becoming standard; BIP/BFLOP class uniprocessors; large scale multiprocessors for special purpose applications; I/O as the most significant computer engineering problem; Hierarchical data servers in everyday use; routine access to archived data around the world; and what else? What do systems such as those we will have this decade imply to those building data analysis systems today? Many of the presumptions of the 1970's and 1980's need to be reexamined in the light of 1990's technology. Author

HST IMAGE RESTORATION: A COMPARISON OF PRE- AND POST-SERVICING MISSION RESULTS Abstract Only **c61**

R. J. Hanisch and J. Mo *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 47 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

A variety of image restoration techniques (e.g., Wiener filter, Lucy-Richardson, MEM) have been applied quite successfully to the aberrated HST images. The HST servicing mission (scheduled for late 1993 or early 1994) will install a corrective optics system (COSTAR) for the Faint Object Camera and spectrographs and replace the Wide Field/Planetary Camera with a second generation instrument (WF/PC-II) having its own corrective elements. The image quality is expected to be improved substantially with these new instruments. What then is the role of image restoration for the HST in the long term? Through a series of numerical experiments using model point-spread functions for both aberrated and unaberrated optics, we find that substantial improvements in image resolution can be obtained for post-servicing mission data using the same or similar algorithms as being employed now to correct aberrated images. Included in our investigations are studies of the photometric integrity of the restoration algorithms and explicit models for HST pointing errors (spacecraft jitter). Author

Europeans are now taking steps to homogenize policies and standardize procedures in electronic publishing (EP) in astronomy and space sciences. This arose from an open meeting organized in Oct. 1991 at Strasbourg Observatory (France) and another business meeting held late Mar. 1992 with the major publishers and journal editors in astronomy and space sciences. The ultimate aim of EP might be considered as the so-called 'intelligent information retrieval' (IIR) or better named 'advanced information retrieval' (AIR), taking advantage of the fact that the material to be published appears at some stage in a machine-readable form. It is obvious that the combination of desktop and electronic publishing with networking and new structuring of knowledge bases will profoundly reshape not only our ways of publishing, but also our procedures of communicating and retrieving information. It should be noted that a world-wide survey among astronomers and space scientists carried out before the October 1991 colloquium on the various packages and machines used, indicated that TEX-related packages were already in majoritarian use in our community. It has also been stressed at each meeting that the European developments should be carried out in collaboration with what is done in the US (STELLAR project, for instance). American scientists and journal editors actually attended both meetings mentioned above. The paper will offer a review of the status of electronic publishing in astronomy and its possible contribution to advanced information retrieval in this field. It will also report on recent meetings such as the 'Astronomy from Large Databases-2 (ALD-2)' conference dealing with the latest developments in networking, in data, information, and knowledge bases, as well as in the related methodologies. Fortran has largely enjoyed prominence for the past few decades as the computer programming language of choice for numerically intensive scientific, engineering, and process control applications. Fortran's well understood static language syntax has allowed resulting parsers and compiler optimizing technologies to often generate among the most efficient and fastest run-time executables, particularly on high-end scalar and vector supercomputers. Computing architectures and paradigms have changed considerably since the last ANSI/ISO Fortran release in 1978, and while FORTRAN 77 has more than survived, it's aged features provide only partial functionality for today's demanding computing environments. The simple block procedural languages have been necessarily evolving, or giving way, to specialized supercomputing, network resource, and object-oriented paradigms. To address these new computing demands, ANSI has worked for the last 12-years with three international public reviews to deliver Fortran 90. Fortran 90 has superseded and replaced ISO FORTRAN 77 internationally as the sole Fortran standard; while in the US, Fortran 90 is expected to be adopted as the ANSI standard this summer, coexisting with ANSI FORTRAN 77 until at least 1996. The development path and current state of Fortran will be briefly described highlighting the many new Fortran 90 syntactic and semantic additions which support (among others): free form source; array syntax; new control structures; modules and interfaces; pointers; derived data types; dynamic memory; enhanced I/O; operator overloading; data abstraction; user optional arguments; new intrinsics for array, bit manipulation, and system inquiry; and enhanced portability through better generic control of underlying system arithmetic models. Examples from dynamical astronomy, signal and image processing will attempt to illustrate Fortran 90's applicability to today's general scalar, vector, and parallel scientific and engineering requirements and object oriented programming paradigms. Time permitting, current work proceeding on the future development of Fortran 2000 and collateral standards will be introduced.

PROGRAMMABILITY IN AIPS++ Abstract Only **c61**
R. M. Hjellming *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 51 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

AIPS++ is an Astronomical Information Processing System being designed and implemented by an international consortium of NRAO and six other radio astronomy institutions in Australia, India, the Netherlands, the United Kingdom, Canada, and the USA. AIPS++ is intended to replace the functionality of AIPS, to be more easily programmable, and will be implemented in C++ using object-oriented techniques. Programmability in AIPS++ is planned at three levels. The first level will be that of a command-line interpreter with characteristics similar to IDL and PV-Wave, but with an intensive set of operations appropriate to telescope data handling, image formation, and image processing. The third level will be in C++ with extensive use of class libraries for both basic operations and advanced applications. The third level will allow input and output of data between external FORTRAN programs and AIPS++ telescope and image databases. In addition to summarizing the above programmability characteristics, this talk will given an overview of the classes currently being designed for telescope data calibration and editing, image formation, and the 'toolkit' of mathematical 'objects' that will perform most of the processing in AIPS++.

The Telescope Image Modelling (TIM) system creates model point spread functions for optical systems based on ray-trace information. The original TIM runs only on VAX/VMS systems, but we are modifying the software to run under IRAF in the STSDAS package in order to make TIM more widely available. The current status of this project will be discussed. Initially the changes will be restricted to the user interface and replacing VAX-specific code. Soon thereafter the IMSL and NAG subroutines will be replaced by public-domain software, and some of the algorithms may be improved.

ASpect: A NEW SPECTRUM AND LINE ANALYSIS PACKAGE FOR IRAF Abstract Only **c61**
S. J. Hulbert, J. D. Eisenhamer, Z. G. Levay, and R. A. Shaw *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 54 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

We examined several publicly available spectral analysis software packages looking for one with enough functionality and versatility to meet the analysis needs of astronomers during the next decade. None of those examined can satisfactorily support the wide variety of panchromatic science programs that are now becoming possible. Furthermore, we concluded that none of these packages can be simply modified to include critical functions because of their original (limited) designs. During the next two years we will write a new spectral analysis package, ASpect, that will incorporate the latest analysis techniques for astronomical spectra in all wavelength domains. The ASpect package has several functional requirements. It must operate on spectra from a wide variety of ground-based and space-based instruments spanning wavelengths from radio to gamma rays. It must accommodate non-linear dispersion relations. It must provide a variety of functions, individually or in combination, with which to fit spectral features and the continuum. It is vitally important that known bad data be masked and that, uncertainties be propagated throughout the calculations in order for astronomers to evaluate the reliability of results. Finally, this new package must provide a powerful, intuitive graphical user interface to handle the burden of data input/output (I/O), on-line 'help,' selection of relevant features for analysis, plotting and graphical interaction, and data base management–all in a comprehensible environment. We anticipate that ASpect will take the form of an external package in IRAF (such as the NOAO and STSDAS packages) and will be layered upon the IRAF virtual Operating System to make it available on as many platforms as possible, while making it resistant to changes in operating systems and compilers. Our choice of IRAF is motivated by its portability, its wide use within the astronomical community, and its rich set of existing user applications.

SPIKE: APPLICATION FOR ASTRO-D MISSION PLANNING Abstract Only **c61**
T. Isobe, M. Johnston, E. Morgan, and G. Clark *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 55 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

SPIKE is a mission planning software system developed by a team of programmers at the STScI for use with the Hubble Space Telescope (HST). SPIKE has been developed for the purpose of automating observatory scheduling to increase the effective utilization and ultimately, scientific return from orbiting telescopes. High-level scheduling strategies using both rule-based and neural network approaches have been incorporated. Graphical displays of activities, constraints, and schedules are an important feature of the system. Although SPIKE was originally developed for the HST, it can be used for other astronomy missions including ground-based observatories. One of the missions that has decided to use SPIKE is ASTRO-D, a Japanese X-ray satellite for which the U.S. is providing a part of the scientific payload. Scheduled to fly in Feb. 1993, its four telescopes will focus X-rays over a wide energy range onto CCD's and imaging gas proportional counters. ASTRO-D will be the first X-ray imaging mission operating over the 0.5-12 keV band with high energy resolution. This combination of capabilities will enable a varied and exciting program of astronomical research to be carried out. ASTRO-D is expected to observe 5 to 20 objects per day and a total of several thousands per year. This requires the implementation of an efficient planning and scheduling system which SPIKE can provide. Although the version of SPIKE that will be used for ASTRO-D mission is almost identical to that used for the HST, there are a few differences. For example, ASTRO-D will use two ground stations for data downlinks, instead of the TDRSS system for data transmission. As a consequence ASTRO-D is constrained by limited on-board data storage capacity to schedule high data-rate observations during periods of frequent high bit rate observations accordingly. We will demonstrate the ASTRO-D version of SPIKE to show what SPIKE can provide and how efficiently it creates an observational schedule. Author (revised)

THE HEASARC GRAPHICAL USER INTERFACE Abstract Only **c61**
N. White, P. Barrett, P. Jacobs, and B. ONeel *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 56 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

An OSF/Motif-based graphical user interface has been developed to facilitate the use of the database and data analysis software packages available from the High Energy Astrophysics Science Archive Research Center (HEASARC). It can also be used as an interface to other, similar, routines. A small number of tables are constructed to specify the possible commands and command parameters for a given set of analysis routines. These tables can be modified by a designer to affect the appearance of the interface screens. They can also be dynamically changed in response to parameter adjustments made while the underlying program is running. Additionally, a communication protocol has been designed so that the interface can operate locally or across a network. It is intended that this software be able to run on a variety of workstations and X terminals.

The Compton Gamma Ray Observatory (CGRO) is an active, earth orbiting satellite consisting of four gamma-ray telescopes. Each telescope is maintained by an independent principal investigator (PI) team, and each PI team has devised separate data formats to handle the needs of their particular instrument. As mandated by NASA, the Compton Observatory Science Support Center (COSSC) intends to archive and distribute PI data to the public in FITS (Flexible Image Transport System) format. To accomplish this task, we at COSSC have been developing a set of general purpose software tools that facilitate the transformation of non-FITS formatted data into FITS format. These tools, known as ToFU (To FITS Utilities), serve as the kernel of our CGRO data conversion software. This presentation describes the problems encountered in transcribing large amounts of data into a standard FITS form and the capabilities of the COSSC-built conversion software designed to perform the transformations.

THE UNIVERSITY OF HAWAII INSTITUTE FOR ASTRONOMY CCD CAMERA CONTROL SYSTEM Abstract Only **c37**
K. T. C. Jim, H. T. Yamada, G. A. Luppino, and R. J. Hlivak *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 58 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The University of Hawaii Institute for Astronomy CCD Camera Control System consists of a NeXT workstation, a graphical user interface, and a fiber optics communications interface which is connected to a San Diego State University CCD controller. The UH system employs the NeXT-resident Motorola DSP 56001 as a real time hardware controller. The DSP 56001 is interfaced to the Mach-based UNIX of the NeXT workstation by DMA and multithreading. Since the SDSU controller also uses the DPS 56001, the NeXT is used as a development platform for the embedded control software. The fiber optic interface links the two DSP 56001's through their Synchronous Serial Interfaces. The user interface is based on the NeXTStep windowing system. It is easy to use and features real-time display of image data and control over all camera functions. Both Loral and Tektronix 2048 x 2048 CCD's have been driven at full readout speeds, and the system is intended to be capable of simultaneous readout of four such CCD's. The total hardware package is compact enough to be quite portable and has been used on five different telescopes on Mauna Kea. The complete CCD control system can be assembled for a very low cost. The hardware and software of the control system has proven to be quite reliable, well adapted to the needs of astronomers, and extensible to increasingly complicated control requirements. AN OBJECT-ORIENTED APPROACH FOR SUPPORTING BOTH X AND TERMINAL INTERFACES Abstract Only **c61**
J. Johnson *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 60 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

While the X Window System is clearly becoming the dominant user interface between display system, there is still a continuing need to support character cell terminal devices. For a user interface application which must support both, it is desirable to be able to use them to their fullest extent, as opposed to simply providing a character-based display within an X window. An object-oriented application framework is presented here which

allows the full capabilities of each system to be used while minimizing and isolating the amount of device-dependent code. Every user interface application consists of two parts: the various components used to display information and accept user input, and the processing of the interaction between these components. Many user interfaces are built around a core set of components such as menus, text entry fields, and forms. For a given application, the interaction between these components is the same regardless of the display system in use. Our approach is to implement each component as an object, accessible via a single public interface. All of the code necesary to implement the component for the desired display system is completely encapsulated within the object. The application is then written as a collection of objects interacting in a device-independent manner with one another. If a display system provides additional capabilities, the application can be extended by adding objects (e.g. for image display in X). We are currently implementing StarView, the user interface to the HST science archive (STDADS) using this approach. StarView will be written in C++ and will use Vermont Views for the terminal interface and OSF/Motif for the X Window interface. Author (revised)

THE APPLICATION OF ARTIFICIAL INTELLIGENCE TO ASTRONOMICAL SCHEDULING PROBLEMS Abstract Only **c63**
Mark D. Johnston *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 61 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Efficient utilization of expensive space- and ground-based observatories is an important goal for the astronomical community; the cost of modern observing facilities is enormous, and the available observing time is much less than the demand from astronomers around the world. The complexity and variety of scheduling constraints and goals has led several groups to investigate how artificial intelligence (AI) techniques might help solve these kinds of problems. The earliest and most successful of these projects was started at Space Telescope Science Institute in 1987 and has led to the development of the Spike scheduling system to support the scheduling of Hubble Space Telescope (HST). The aim of Spike at STScI is to allocate observations to timescales of days to a week observing all scheduling constraints and maximizing preferences that help ensure that observations are made at optimal times. Spike has been in use operationally for HST since shortly after the observatory was launched in Apr. 1990. Although developed specifically for HST scheduling, Spike was carefully designed to provide a general framework for similar (activity-based) scheduling problems. In particular, the tasks to be scheduled are defined in the system in general terms, and no assumptions about the scheduling timescale are built in. The mechanisms for describing, combining, and propagating temporal and other constraints and preferences are quite general. The success of this approach has been demonstrated by the application of Spike to the scheduling of other satellite observatories: changes to the system are required only in the specific constraints that apply, and not in the framework itself. In particular, the Spike framework is sufficiently flexible to handle both long-term and short-term scheduling, on timescales of years down to minutes or less. This talk will discuss recent progress made in scheduling search techniques, the lessons learned from early HST operations, the application of Spike to other problem domains, and plans for the future evolution of the system. A GENERIC ARCHIVE PROTOCOL AND AN IMPLEMENTATION Abstract Only **c82**
J. M. Jordan, D. G. Jennings, T. A. McGlynn, N. G. Ruggiero, and T. A. Serlemitsos *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 62 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Archiving vast amounts of data has become a major part of every scientific space mission today. The Generic Archive/Retrieval Services Protocol (GRASP) addresses the question of how to archive the data collected in an environment where the underlying hardware archives may be rapidly changing. GRASP is a device independent specification defining a set of functions for storing and retrieving data from an archive, as well as other support functions. GRASP is divided into two levels: the Transfer Interface and the Action Interface. The Transfer Interface is computer/archive independent code while the Action Interface contains code which is dedicated to each archive/computer addressed. Implementations of the GRASP specification are currently available for DECstations running Ultrix, Sparcstations running SunOS, and microVAX/VAXstation 3100's. The underlying archive is assumed to function as a standard Unix or VMS file system. The code, written in C, is a single suite of files. Preprocessing commands define the machine unique code sections in the device interface. The implementation was written, to the greatest extent possible, using only ANSI standard C functions. THE ADAM ENVIRONMENT AND TRANSPUTERS Abstract Only **c61**
B. D. Kelly, J. M. Stewart, and B. V. McNally *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 63 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The ADAM environment is both used for data analysis by Starlink and for data acquisition by the UK-involved observatories in Australia, Hawaii, and the Canary Islands. ADAM was originally hosted under VAX/VMS but is now at an advanced stage of a Unix port. ADAM comprises a parameter system, hierarchical data system, noticeboard system, error handling system, and other components. Originally a multi-tasking single processor environment, it has been enhanced to a multiprocessor environment using local or wide area networking. The Royal Observatory Edinburgh is producing a transputer version of the ADAM kernel to allow instruments which make use of transputers for data acquisition/control to integrate more closely with the ADAM software running at the telescopes. Communication into the transputer system is based on Ethernet carrying TCP/IP, which eases development toward a network of mixed VMS/Unix/transputer Telescope systems. The transputer system is being applied to instruments under development for the UKIRT and JCMT telescopes. Author (revised)

CCD DATA ACQUISITION SYSTEMS AT LICK AND KECK OBSERVATORIES Abstract Only **c82**
R. I. Kibrick, R. J. Stover, and A. R. Conrad (Keck Observatory, Mauna Kea, HI.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 64 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

This paper will describe and compare two distinct but related CCD data acquisition systems (DAS) currently under development at Lick and Keck Observatories. Although these two systems have a number of major architectural differences, they share a considerable amount of common hardware and software. Both of these new systems build on a large body of proven software that is the foundation of the existing CCD DAS currently in use at Lick Observatory. Both will provide support for reading up to four on-chip amplifiers per CCD and/or reading out mosaics of CCD chips. In addition, they will provide the capability for interactive, real-time adjustment of CCD waveforms for engineering purposes. Each of these two systems is composed of three major subsystems: (1) an instrument computer and its software; (2) a data capture computer and its software; and (3) a CCD/dewar controller and its software. The instrument computer is a Unix workstation, and the functions it provides include user interfaces, the interactive real-time display of CCD images, and the recording of image and FITS header data to disk and/or tape. The data capture computer is responsible for the packaging and high-speed transfer of the CCD pixel data stream into a bulk RAM, and the subsequent transfer of this data to the instrument computer. The CCD/dewar controller generates the waveforms for clocking the CCD, digitizes the pixel data, and transmits it via high-speed link to the data capture computer. It is also responsible for monitoring and controlling the dewar temperature and cryogen levels. Given the number of different types of processors and high-speed data links employed in both systems, a major emphasis of this paper will be on the various forms of interprocessor communications utilized for data transfer and distributed process synchronization. THE DIGITAL ARCHIVE OF THE INTERNATIONAL HALLEY WATCH Abstract Only **c82**
D. A. Klinglesmith, III, M. B. Niedner, E. Grayzeck (Maryland Univ., College Park.), M. Aronsson (Jet Propulsion Lab., Cape Canaveral, FL.), R. L. Newburn (Jet Propulsion Lab., Cape Canaveral, FL.), and A. Warnock, III (Hughes STX, Inc., Greenbelt, MD.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 65 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The International Halley Watch was established to coordinate, collect, archive, and distribute the scientific data from Comet P/Halley that would be obtained from both the ground and space. This paper describes one of the end products of that effort, namely the IHW Digital Archive. The IHW Digital Archive consists of 26 CD-ROM's containing over 32 gigabytes of data from the 9 IHW disciplines as well as data from the 5 spacecraft missions flown to comet P/Haley and P/Giacobini-Zinner. The total archive contains over 50,000 observations by 1,500 observers from at least 40 countries. The first 24 CD's, which are currently available, contain data from the 9 IHW disciplines. The two remaining CD's will have the spacecraft data and should be available within the next year. A test CD-ROM of these data has been created and is currently under review.

DECONVOLUTION OF HUBBLE SPACE TELESCOPE IMAGES USING SIMULATED POINT SPREAD FUNCTIONS Abstract Only **c82**
J. E. Krist and H. Hasan *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 66 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Presented is a study of the use of simulated point spread functions (PSF's) to deconvolve Hubble Space Telescope images. We concentrate on images from the Wide Field and Planetary Camera (WFPC) and examine the affect of position dependence of the PSF and the telescope focus position on deconvolutions. Comparisons will be made to what will be expected from WFPC 2, which will include corrective optics. Since PSF's can be simulated for any specific observation, with the added advantage of being noise free and the ability to subsample them, they may be more suitable for deconvolution than observed ones in some cases. And since finding a suitable observed PSF may be difficult, simulated ones may be easier to use.

Tiny Tim is a program which simulates Hubble Space Telescope imaging camera PSF's. It is portable (written and distributed in C) and is reasonably fast. It can model the WFPC, WFPC 2, FOC, and COSTAR corrected FOC cameras. In addition to aberrations such as defocus and spherical, it also includes WFPC obscuration shifting, mirror zonal error maps, and jitter. The program has been used at a number of sites for deconvolving HST images. Tiny Tim is available via anonymous ftp on stsci.edu in the directory software/tinytim.

In collaboration with the NASA Scientific and Technical Information System, the NASA Astrophysics Data System (ADS) is establishing a service to provide access to the literature abstracts relevant to astronomy in the NASA Scientific and Technical Aerospace Reports and the International Aerospace Abstracts (together also known as NASA RECON). The service will include several sophisticated retrieval methods, which may be combined. Included will be methods to perform relevancy ranking from natural language queries, synonym and misspelling recognition, author name translation (e.g. for multiple transliteration possibilities), and other features. The capabilities of the current release will be shown, and the plans for the near future will be discussed.

IDL (Interactive Data Language) is a commercial programming, plotting, and image display language, which is widely used in astronomy. The IDL Astronomy User's Library is a central repository of over 400 astronomy-related IDL procedures accessible via anonymous FTP. The author will overview the use of IDL within the astronomical community and discuss recent enhancements at the IDL astronomy library. These enhancements include a fairly complete I/O package for FITS images and tables, an image deconvolution package and an image mosaic package, and access to IDL Open Windows/Motif widgets interface. The IDL Astronomy Library is funded by NASA through the Astrophysics Software and Research Aids Program.

Avail: CASI HC A01/MF A02

The Energetic Gamma Ray Telescope Experiment (EGRET) on the Compton Gamma Ray Observatory has been in orbit for more than a year and is being used to map the full sky for gamma rays in a wide energy range from 30 to 20,000 MeV. Already these measurements have resulted in a wide range of exciting new information on quasars, pulsars, galactic sources, and diffuse gamma ray emission. The central part of the analysis is done with sky maps that typically cover an 80 x 80 degree section of the sky for an exposure time of several days. Specific software developed for this program generates the counts, exposure, and intensity maps. The analysis is done on a network of UNIX based workstations and takes full advantage of a custom-built user interface called X-dialog. The maps that are generated are stored in the FITS format for a collection of energies. These, along with similar diffuse emission background maps generated from a model calculation, serve as input to a maximum likelihood program that produces maps of likelihood with optional contours that are used to evaluate regions for sources. Likelihood also evaluates the background corrected intensity at each location for each energy interval from which spectra can be generated. Being in a standard FITS format permits all of the maps to be easily accessed by the full complement of tools available in several commercial astronomical analysis systems. In the EGRET case, IDL is used to produce graphics plots in two and three dimensions and to quickly implement any special evaluation that might be desired. Other custom-built software, such as the spectral and pulsar analyses, take advantage of the XView toolkit for display and Postscript output for the color hard copy. This poster paper outlines the data flow and provides examples of the user interfaces and output products. It stresses the advantages that are derived from the integration of the specific instrument-unique software and powerful commercial tools for graphics and statistical evaluation. This approach has several proven advantages including flexibility, a minimum of development effort, ease of use, and portability.

SIMBAD QUALITY-CONTROL Abstract Only **c82**
Soizick Lesteven *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 71 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The astronomical database SIMBAD developed at the Centre de donnees astronomiques de Strasbourg presently contains 760,000 objects (stellar and non-stellar). It has the unique characteristic of being structured specifically for astronomical objects. All types of heterogeneous data (bibliographic references, measurements, and sets of identification) are connected with each object. The attributes that define quality of the database include the following. Reliability: cross-identification should not rely upon just exact values object coordinates. It also means that information attached to one simple object should be consistent. The existing data must be controlled in order to start with a reliable base and to cross-identify new data assuring the quality as data grows. Exhaustivity: delays between publication of new informations and their inclusion in the database should be as short as possible. The integrity of the database has to be maintained as data accumulates. Taking the amount of data into consideration and the rate of new data production, it is necessary to use automatic methods. One of the possibilities is to use multivariate data analysis. The factor-space is a n-dimensional relevancy space which is described by the n-axes representing a set of n subject matter headings; the words and phrases can be used to scale the axes and the documents are then a vector average of the terms within them. The application reported herein is based on the NASA-STI bibliographical database. The selected data concern astronomy, astrophysics, and space radiation (102,963 references from 1975 to 1991 included 8070 keywords). The F-space is built from this bibliographical data. By comparing the F-space position obtained from the NASA-STI keywords with the F-space position obtained from the SIMBAD references, the authors will be able to show whether it is possible to retrieve information with a restricted set of words only. If the comparison is valid, this will be a way to enter bibliographic information in the SIMBAD quality control process. Furthermore, it is possible to connect the physical measurements of stars from SIMBAD to literature concerning these stars from the NASA-STI abstracts. The physical properties of stars (e.g. UBV colors) are not randomly distributed. Stars are distributed among different clusters in a physical parameter space. The authors will show that there are some relations between this classification and the literature concerning these objects clusters in a factor space. They will investigate the nature of the relationship between the SIMBAD measurements and the bibliography. These would be new relationships that are not pre-established by an astronomer. In addition, the bibliography could be neutral information that can be used in combination with the measured parameters.

DATA INDEXING TECHNIQUES FOR THE EUVE ALL-SKY SURVEY Abstract Only **c82**
J. Lewis, V. Saba, and C. Dobson *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 72 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

This poster describes techniques developed for manipulating large full-sky data sets for the Extreme Ultraviolet Explorer project. The authors have adapted the quatrilateralized cubic sphere indexing algorithm to allow us to efficiently store and process several types of large data sets, such as full-sky maps of photon counts, exposure time, and count rates. A variation of this scheme is used to index sparser data such as individual photon events and viewing times for selected areas of the sky, which are eventually used to create EUVE source catalogs. THE KECK TASK LIBRARY (KTL) Abstract Only **c82**
W. F. Lupton and A. R. Conrad *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 73 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

KTL is a set of routines which eases the job of writing applications which must interact with a variety of underlying sub-systems (known as services). A typical application is an X Window user interface coordinating telescope and instruments. In order to connect to a service, application code specifies a service name--typically an instrument name--and a style, which defines the way in which the application will interact with the service. Two styles are currently supported: keyword, where the application reads and writes named keywords and the resulting inter-task message traffic is hidden; and message, where the application deals directly with messages. The keyword style is intended mainly for user interfaces, and the message style is intended mainly for lower-level applications. KTL applications are event driven: a typical application first connects to all its desired services, then expresses interest in specified events. The application then enters an event dispatch loop in which it waits for events and calls the appropriate service's event-handling routine. Each event is associated with a call-back routine which is invoked when the event occurs. Call-back routines may (and typically do) interact with other sub-systems and KTL provides the means of doing so without blocking the application (vital for X Window user interfaces). This approach is a marriage of ideas culled from the X window, ADAM, Keck instrument, and Keck telescope control systems. A novel feature of KTL is that it knows nothing about any services or styles. Instead it defines a generic set of routines which must be implemented by all services and styles (essentially open(), ioctl(), read(), write(), event(), and close()) and activates sharable libraries at run-time. Services have been implemented (in both keyword and message styles) for HIRES (the Keck high resolution echelle spectrograph built by Lick Observatory), LWS (the Keck long wavelength spectrometer built by UC San Diego), and the Keck telescope. Each of these implementations uses different underlying message systems: the Lick MUSIC system, RPC's, and direct sockets (respectively). Services for the remaining three front-line Keck instruments will be implemented over the next few months. Author (revised)

Isaac is a task in the NSO external package for IRAF. A descendant of a FORTRAN program written to analyze data from a Fourier transform spectrometer, the current implementation has been generalized sufficiently to make it useful for general spectral analysis and other one dimensional data analysis tasks. The user interface for Isaac is implemented as an interpreted mini-language containing a powerful, programmable vector calculator. Built-in commands provide much of the functionality needed to produce accurate line lists from input spectra. These built-in functions include automated spectral line finding, least squares fitting of Voigt profiles to spectral lines including equality constraints, various filters including an optimal filter construction tool, continuum fitting, and various I/O functions.

THE NSO FTS DATABASE PROGRAM AND ARCHIVE (FTSDBM) Abstract Only **c61**
D. M. Lytle *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 75 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Data from the NSO Fourier transform spectrometer is being re-archived from half inch tape onto write-once compact disk. In the process, information about each spectrum and a low resolution copy of each spectrum is being saved into an on-line database. FTSDBM is a simple database management program in the NSO external package for IRAF. A command language allows the FTSDBM user to add entries to the database, delete entries, select subsets from the database based on keyword values including ranges of values, create new database files based on these subsets, make keyword lists, examine low resolution spectra graphically, and make disk number/file number lists. Once the archive is complete, FTSDBM will allow the database to be efficiently searched for data of interest to the user and the compact disk format will allow random access to that data. AXAF USER INTERFACES FOR HETEROGENEOUS ANALYSIS ENVIRONMENTS Abstract Only **c61**

Eric Mandel, John Roll, and Mark S. Ackerman (Massachusetts Inst. of Tech., Cambridge.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 76 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The AXAF Science Center (ASC) will develop software to support all facets of data center activities and user research for the AXAF X-ray Observatory, scheduled for launch in 1999. The goal is to provide astronomers with the ability to utilize heterogeneous data analysis packages, that is, to allow astronomers to pick the best packages for doing their scientific analysis. For example, ASC software will be based on IRAF, but non-IRAF programs will be incorporated into the data system where appropriate. Additionally, it is desired to allow AXAF users to mix ASC software with their own local software. The need to support heterogeneous analysis environments is not special to the AXAF project, and therefore finding mechanisms for coordinating heterogeneous programs is an important problem for astronomical software today. The approach to solving this problem has been to develop two interfaces that allow the scientific user to run heterogeneous programs together. The first is an IRAF-compatible parameter interface that provides non-IRAF programs with IRAF's parameter handling capabilities. Included in the interface is an application programming interface to manipulate parameters from within programs, and also a set of host programs to manipulate parameters at the command line or from within scripts. The parameter interface has been implemented to support parameter storage formats other than IRAF parameter files, allowing one, for example, to access parameters that are stored in data bases. An X Windows graphical user interface called 'agcl' has been developed, layered on top of the IRAF-compatible parameter interface, that provides a standard graphical mechanism for interacting with IRAF and non-IRAF programs. Users can edit parameters and run programs for both non-IRAF programs and IRAF tasks. The agcl interface allows one to communicate with any command line environment in a transparent manner and without any changes to the original environment. For example, the authors routinely layer the GUI on top of IRAF, ksh, SMongo, and IDL. The agcl, based on the facilities of a system called Answer Garden, also has sophisticated support for examining documentation and help files, asking questions of experts, and developing a knowledge base of frequently required information. Thus, the GUI becomes a total environment for running programs, accessing information, examining documents, and finding human assistance. Because the agcl can communicate with any command-line environment, most projects can make use of it easily. New applications are continually being found for these interfaces. It is the authors' intention to evolve the GUI and its underlying parameter interface in response to these needs - from users as well as developers - throughout the astronomy community. This presentation describes the capabilities and technology of the above user interface mechanisms and tools. It also discusses the design philosophies guiding the work, as well as hopes for the future. Author (revised)

GammaCore: THE COMPTON OBSERVATORY RESEARCH ENVIRONMENT Abstract Only **c82**

T. A. McGlynn, D. G. Jennings, J. M. Jordan, N. Ruggiero, and T. A. Serlemitsos *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 78 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The Compton Observatory Science Support Center (COSSC) is developing a coherent analysis environment for the analysis of Compton and other gamma-ray astronomy data. This environment, GammaCore, allows the astronomer to access the data analysis systems developed at the Principal Investigator (PI) sites for the four Compton Observatory instruments. In addition users have access to standard astronomical tools such as IRAF, IDL, and XANADU. The user interface of GammaCore is the AGCL (AnswerGarden Command Language), developed at the AXAF Science Center. The parameter interface supported by the AGCL allows GammaCore to access all PI software systems in a uniform fashion. These systems are quite different, having been developed independently on heterogeneous systems without much concern for general portability. The data kibitzer concept, where a window running in a specific PI environment is controlled by the AGCL, has been used extensively. Users can choose to view what is going on in the native environment, to use the window to control PI software directly, or to ignore the PI systems entirely and to work only through the homogeneous AGCL interface. Software developed at the COSSC is also integrated within GammaCore. Extensive facilities for conversions of PI data formats to and from FITS have been developed. Access to the Compton data archive and catalogs will also be completely integrated with the GammaCore. Users can retrieve any publicly available Compton data. This paper examines the issues that have arisen in attempting to meld these widely diverse systems. The advantages and limitations of the parameter interface and the kibitzer are discussed along with issues of data portability, documentation, and the feasibility of multi-instrument analysis. Limited capabilities are now available within GammaCore with significant enhancements planned over the coming year. An implementation including all PI systems will be available within that time. Instructions on how to access GammaCore and how to get more information are given.

WILBUR: A LOW-COST CCD CAMERA SYSTEM FOR MDM OBSERVATORY Abstract Only **c35**

M. R. Metzger, G. A. Luppino (Istituto di Fisica dell Atmosfera, Rome, Italy.), and J. L. Tonry *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 79 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The recent availability of several 'off-the-shelf' components, particularly CCD control electronics from SDSU, has made it possible to put together a flexible CCD camera system at relatively low cost and effort. The authors describe Wilbur, a complete CCD camera system constructed for the Michigan-Dartmouth-MIT Observatory. The hardware consists of a Loral 2048(exp 2) CCD controlled by the SDSU electronics, an existing dewar design modified for use at MDM, a Sun Sparcstation 2 with a commercial high-speed parallel controller, and a simple custom interface between the controller and the SDSU electronics. The camera is controlled from the Sparcstation by software that provides low-level I/O in real time, collection of additional information from the telescope, and a simple command interface for use by an observer. Readout of the 2048(exp 2) array is complete in under two minutes at 5 e(sup -) read noise, and readout time can be decreased at the cost of increased noise. The system can be easily expanded to handle multiple CCD's/multiple readouts, and can control other dewars/CCD's using the same host software. Author (revised)

SKYMAP: EXPLORING THE UNIVERSE IN SOFTWARE Abstract Only **c61**

D. J. Mink *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 80 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

SKYMAP is a computer program which produces maps of arbitrary portions of the sky in a variety of projections and coordinate systems. Over the past ten years it has been used to produce finder charts for occultations by planets, display scan and image data from the Spacelab 2 Infrared Telescope, and make maps of fields for astronomical observations

at X-ray, optical, infrared, and radio wavelengths. It can display multiple source catalogs, including the HST Guide Star Catalog, as well as solar system objects with astrometric accuracy using the JPL DE-130 ephemeris or tabulated positions. SKYMAP can be tuned to a specific task using an ASCII parameter file which controls how information is displayed on any Tektronix-compatible graphics display. The program contains a variety of interactive graphic and image processing features and has been ported to a variety of computer systems. A recent project visually demonstrates source density variation in various commonly-used all-sky catalogs.

STARBASE: DATABASE SOFTWARE FOR THE AUTOMATED PLATE SCANNER Abstract Only c61

S. C. Odewahn, R. M. Humphreys, and P. Thurmes *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 81 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The Automated Plate Scanner (APS) of the University of Minnesota, a unique high speed 'flying spot' laser scanner, is currently being used to scan and digitize the 936 O and E plate pairs of the first epoch Palomar Sky Survey. The resultant database will be used to produce a catalog of approximately a billion stars and several million galaxies. The authors describe the ongoing development of a dedicated APS database management system which will be made available to the astronomical community via INTERNET. A specialized DBMS called STARBASE has been written to provide fast access to the hundreds of millions of images collected by the APS. This system provides an initial reduction mode for parameterizing APS images and classifying image types using a novel set of neural network image classifiers. A second analysis mode, which will be that commonly used by the general user, provides for searches of the database which may be constrained by any combination of physical and positional parameters. Through the use of pointer hash trees, the system has been optimized for extremely fast positional searches using either right ascension and declination on the sky or linear X and Y positions on the POSS field. In addition to fast data retrieval, the system provides a graphical interface for displaying scatter plots or histograms of the collected data. In addition, a specialized image display system is being developed to allow the user to view densitometric data for all objects classified as extended by the neural network system. Finally, STARBASE has a flexible programmable interface which allows other programs to access information in the database. This allows users to write applications suited to their particular needs to process APS data. Author (revised)

XPI: THE XANADU PARAMETER INTERFACE Abstract Only c61

N. White, P. Barrett, B. ONeel, and P. Jacobs *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 82 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

XPI is a table driven parameter interface which greatly simplifies both command driven programs such as BROWSE and XIMAGE as well as stand alone single-task programs. It moves all of the syntax and semantic parsing of commands and parameters out of the users code into common code and externally defined tables. This allows the programmer to concentrate on writing the code unique to the application rather than reinventing the user interface and for external graphical interfaces to interface with no changes to the command driven program. XPI also includes a compatibility library which allows programs written using the IRAF host interface (Mandel and Roll) to use XPI in place of the IRAF host interface.

EVALUATION OF RDBMS PACKAGES FOR USE IN ASTRONOMY Abstract Only c82

C. G. Page and A. C. Davenhall *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 83 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Tabular data sets arise in many areas of astronomical data analysis, from raw data (such as photon event lists) to final results (such as source catalogs). The Starlink catalog access and reporting package, SCAR, was originally developed to handle IRAS data and it has been the principal relational DBMS in the Starlink software collection for several years. But SCAR has many limitations and is VMS-specific, while Starlink is in transition from VMS to Unix. Rather than attempt a major re-write of SCAR for Unix, it seemed more sensible to see whether any existing database packages are suitable for general astronomical use. The authors first drew up a list of desirable properties for such a system and then used these criteria to evaluate a number of packages, both free ones and those commercially available. It is already clear that most commercial DBMS packages are not very well suited to the requirements; for example, most cannot carry out efficiently even fairly basic operations such as joining two catalogs on an approximate match of celestial positions. This paper reports the results of the evaluation exercise and notes the problems in using a standard DBMS package to process scientific data. In parallel with this the authors have started to develop a simple database engine that can handle tabular data in a range of common formats including simple direct-access files (such as SCAR and Exosat DBMS tables) and FITS tables (both ASCII and binary).

SOME PRACTICABLE APPLICATIONS OF QUADTREE DATA STRUCTURES/REPRESENTATION IN ASTRONOMY Abstract Only c61

L. Pasztor *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 84 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Development of quadtree as hierarchical data structuring technique for representing spatial data (like points, regions, surfaces, lines, curves, volumes, etc.) has been motivated to a large extent by storage requirements of images, maps, and other multidimensional (spatially structured) data. For many spatial algorithms, time-efficiency of quadtrees in terms of execution may be as important as their space-efficiency concerning storage conditions. Briefly, the quadtree is a class of hierarchical data structures which is based on the recursive partition of a square region into quadrants and sub-quadrants until a predefined limit. Beyond the wide applicability of quadtrees in image processing, spatial information analysis, and building digital databases (processes becoming ordinary for the astronomical community), there may be numerous further applications in astronomy. Some of these practicable applications based on quadtree representation of astronomical data are presented and suggested for further considerations. Examples are shown for use of point as well as region quadtrees. Statistics of different leaf and non-leaf nodes (homogeneous and heterogeneous sub-quadrants respectively) at different levels may provide useful information on spatial structure of astronomical data in question. By altering the principle guiding the decomposition process, different types of spatial data may be focused on. Finally, a sampling method based on quadtree representation of an image is proposed which may prove to be efficient in the elaboration of sampling strategy in a region where observations were carried out previously either with different resolution or/and in different bands.

DEVELOPMENT OF THE FITS TOOLS PACKAGE FOR MULTIPLE SOFTWARE ENVIRONMENTS Abstract Only c61

W. D. Pence and J. K. Blackburn *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 85 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The HEASARC is developing a package of general purpose software for analyzing data files in FITS format. This paper describes the design philosophy which makes the software both machine-independent (it runs on VAXs, Suns, and DEC-stations) and software environment-independent. Currently the software can be compiled and linked to produce IRAF tasks, or alternatively, the same source code can be used to generate stand-alone tasks using one of two implementations of a user-parameter interface library. The machine independence of the software is achieved by writing the source code in ANSI standard Fortran or C, using the machine-independent FITSIO subroutine interface for all data file I/O, and

using a standard user-parameter subroutine interface for all user I/O. The latter interface is based on the Fortran IRAF Parameter File interface developed at STScI. The IRAF tasks are built by linking to the IRAF implementation of this parameter interface library. Two other implementations of this parameter interface library, which have no IRAF dependencies, are now available which can be used to generate stand-alone executable tasks. These stand-alone tasks can simply be executed from the machine operating system prompt either by supplying all the task parameters on the command line or by entering the task name after which the user will be prompted for any required parameters. A first release of this FTOOLS package is now publicly available. The currently available tasks are described, along with instructions on how to obtain a copy of the software.

EFFICIENT TRANSFER OF IMAGES OVER NETWORKS Abstract Only **c32**

J. W. Percival and R. L. White (Space Telescope Science Inst., Baltimore, MD.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 86 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Effective remote observing requires sending large images over long distances. The usual approach to the transfer problem is to require high bandwidth transmission links, which are expensive to install and operate. An alternative approach is to use existing low-bandwidth connections, such as phone lines or the Internet, in a highly efficient manner by compressing the images. The combined use of existing low-cost infrastructure and standard networking software means that remote observing can be made practical even for small observatories with limited network resources. The authors have implemented such a scheme based on the H-transform compression method developed for astronomical images, which are often resistant to compression because they are noisy. The H-transform can be used for either lossy or lossless compression, and compression factors of at least 10 can be achieved with no noticeable losses in the astrometric or photometric properties of the compressed images. The H-transform allows us to organize the information in an image so that the 'useful' information can be sent first, followed by the noise, which makes up the bulk of the transmission. The receiver can invert a partially received set of H-coefficients, creating an image that improves with time. The H-transform is particularly well-suited to this style of incremental reconstruction, because the spatially localized nature of the basis functions of the H-transorm prevents the appearance of artifacts such as ringing around point sources and edges. The authors' implementation uses the WIYN Telescope Control System's TCP-based communications protocol. An 800x800 16-bit astronomical image was sent over a 2400 baud connection, which would normally take about 71 minutes; after only 60 seconds, the partially received H-transform produced an image that did not differ appreciably from the original. This poster presents a quantification of the efficiencies, as well as examples of images reconstructed from partial data. Author (revised)

THE EUROPEAN SOUTHERN OBSERVATORY-MIDAS TABLE FILE SYSTEM Abstract Only **c82**

M. Peron and P. Grosbol *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 87 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The new and substantially upgraded version of the Table File System in MIDAS is presented as a scientific database system. MIDAS applications for performing database operations on tables are discussed, for instance, the exchange of the data to and from the TFS, the selection of objects, the uncertainty joins across tables, and the graphical representation of data. This upgraded version of the TFS is a full implementation of the binary table extension of the FITS format; in addition, it also supports arrays of strings. Different storage strategies for optimal access of very large data sets are implemented and are addressed in detail. As a simple relational database, the TFS may be used for the management of personal data files. This opens the way to intelligent pipeline processing of large amounts of data. One of the key features of the Table File System is to provide also an extensive set of tools for the analysis of the final results of a reduction process. Column operations using standard and special mathematical functions as well as statistical distributions can be carried out; commands for linear regression and model fitting using nonlinear least square methods and user-defined functions are available. Finally, statistical tests of hypothesis and multivariate methods can also operate on tables.

AN X RAY ARCHIVE ON YOUR DESK: THE EINSTEIN CD-ROM'S Abstract Only **c82**

A. Prestwich, J. McDowell, D. Plummer, K. Manning, and M. Garcia *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 88 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Data from the Einstein Observatory imaging proportional counter (IPC) and high resolution imager (HRI) were released on several CD-ROM sets. The sets released so far include pointed IPC and HRI observations in both simple image and detailed photon event list format, as well as the IPC slew survey. With the data on these CD-ROMS's the user can perform spatial analysis (e.g., surface brightness distributions), spectral analysis (with the IPC event lists), and timing analysis (with the IPC and HRI event lists). The next CD-ROM set will contain IPC unscreened data, allowing the user to perform custom screening to recover, for instance, data during times of lost aspect data or high particle background rates. ADAPTIVE FILTERING OF ECHELLE SPECTRA OF DISTANT QUASARS Abstract Only

A. Priebe, D.-E. Liebscher, H. Lorenz, and G.-M. Richter *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 89 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The study of the Ly alpha - forest of distant (approximately greater than 3) Quasars is an important tool in obtaining a more detailed picture of the distribution of matter along the line of sight and thus of the general distribution of matter in the Universe and is therefore of important cosmological significance. Obviously, this is one of the tasks where spectral resolution plays an important role. The spectra used were obtained with the EFOSC at the ESO 3.6m telescope. Applying for the data reduction the standard Echelle procedure, as it is implemented for instance in the MIDAS-package, one uses stationary filters (e.g. median) for noise and cosmic particle event reduction in the 2-dimensional Echelle image. These filters are useful if the spatial spectrum of the noise reaches essentially higher frequencies then the highest resolution features in the image. Otherwise the resolution in the data will be degraded and the spectral lines smoothed. However, in the Echelle spectra the highest resolution is already in the range of one or a few pixels and therefore stationary filtering means always a loss of resolution. An Echelle reduction procedure on the basis of a space variable filter described which recognizes the local resolution in the presence of noise and adapts to it is developed. It was shown that this technique leads to an improvement in resolution by a factor of 2 with respect to standard procedures. Author (revised)

THE EXOSAT DATABASE AND ARCHIVE Abstract Only **c82**

A. P. Reynolds and A. N. Parmar *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 90 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The EXOSAT database provides on-line access to the results and data products (spectra, images, and lightcurves) from the EXOSAT mission as well as access to data and logs from a number of other missions (such as EINSTEIN, COS-B, ROSAT, and IRAS). In addition, a number of familiar optical, infrared, and x ray catalogs, including the Hubble Space Telescope (HST) guide star catalog are available. The complete database is located at the EXOSAT observatory at ESTEC in the Netherlands and is accessible remotely via a captive account. The database management system was specifically developed to efficiently access the database and to allow the user to perform statistical studies on large samples of astronomical objects as well as to retrieve scientific and bibliographic

information on single sources. The system was designed to be mission independent and includes timing, image processing, and spectral analysis packages as well as software to allow the easy transfer of analysis results and products to the user's own institute. The archive at ESTEC comprises a subset of the EXOSAT observations, stored on magnetic tape. Observations of particular interest were copied in compressed format to an optical jukebox, allowing users to retrieve and analyze selected raw data entirely from their terminals. Such analysis may be necessary if the user's needs are not accommodated by the products contained in the database (in terms of time resolution, spectral range, and the finesse of the background subtraction, for instance). Long-term archiving of the full final observation data is taking place at ESRIN in Italy as part of the ESIS program, again using optical media, and ESRIN have now assumed responsibility for distributing the data to the community. Tests showed that raw observational data (typically several tens of megabytes for a single target) can be transferred via the existing networks in reasonable time.

THE ISO SWS ON-LINE SYSTEM Abstract Only **c61**

P. R. Roelfsema, D. J. M. Kester, P. R. Wesselius, E. Wieprech, and N. Sym *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 91 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The software which is currently being developed for the Short Wavelength Spectrometer (SWS) of the Infrared Space Observatory (ISO) is described. The spectrometer has a wide range of capabilities in the 2-45 micron infrared band. SWS contains two independent gratings, one for the long and one for the short wavelength section of the band. With the gratings a spectral resolution of approximately 1000 to approximately 2500 can be obtained. The instrument also contains two Fabry-Perault's yielding a resolution between approximately 1000 and approximately 20000. Software is currently being developed for the acquisition, calibration, and analysis of SWS data. The software is firstly required to run in a pipeline mode without human interaction, to process data as they are received from the telescope. However, both for testing and calibration of the instrument as well as for evaluation of the planned operating procedures the software should also be suitable for interactive use. Thirdly the same software will be used for long term characterization of the instrument. The software must work properly within the environment designed by the European Space Agency (ESA) for the spacecraft operations. As a result strict constraints are put on I/O devices, throughput etc. Author (revised)

KHOROS SOFTWARE SPECIFICATION FORMAT AND INTEROPERABILITY Abstract Only **c61**

A. H. Rots *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 92 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Khoros defines formats for User Interface Specification (UIS) and Program Specification (PS) files. From such files, its code generator, Ghostwriter, creates source files and documentation. The great advantage of the system is that the code fragments that make up part of the PS file are purely generic. All Khoros-related code is created by the code generator; this includes all user interface code. As a matter of fact, both specification files are very generic in nature. Thus, one could imagine using it as the basis for other software systems. A case is made that writing a code generator that would create IRAF-compatible code from the Khoros UIS and PS files is fairly trivial. Another aspect of the Khoros system conventions concerns the way execution commands are generated by the user interface and the actual syntax of those commands. The protocols are such that interoperability at the level of executable modules is readily possible.

SPATIAL REGION FILTERING IN IRAF/PROS Abstract Only **c61**

Eric Mandel, John Roll, Dennis Schmidt, Mike VanHilst (Washington Univ., Seattle.), and Richard Burg (Johns Hopkins Univ., Baltimore, MD.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 93 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

In order to analyze x ray data, it is nearly always necessary to extract source and background events from a data set. Typically, this is done by defining geometric spatial regions of the data set to describe the source and background. For example, one might wish to extract source events from a circular or elliptical region centered at a particular pixel, and background events from a circular or elliptical annulus whose inner radius matches the source region. At the same time, it might be necessary to exclude one or more nearby sources from the source or background region in question. Thus, it might be necessary to define a pie-shaped region or even an entirely irregularly-shaped region to exclude. A spatial filtering scheme called REGIONS was implemented in IRAF/PROS to support these and other types of spatial region extraction. It allows users to create a spatial mask by specifying one or more ASCII geometric shape descriptors (box, circle, ellipse, pie, point, annulus, and polygon) as regions to be included or excluded in the mask. In addition, two or more shapes can be combined using Boolean algebra to create an infinite variety of sophisticated regions. Each geometric shape has a specific set of parameters that describe that shape. For example, a circle is described by a center and a radius, while a box is described by a center, length, width, and rotation angle. These quantities can be specified in units of pixels or, in cases where the target image contains world coordinate system information, they can be described in units such as RA and Dec. Users can create region mask files by feeding an ASCII region descriptor to the IRAF/PROS picreate task. Temporary masks can also be created from ASCII region descriptors by individual applications that call the routines in the region creation library. This library implements a yacc-based region parser that compiles the ASCII descriptors into 'software CPU' instructions which are then executed to create the mask. The mask created from these region descriptors is a standard IRAF PLIO mask. It can be combined with other PLIO masks (e.g., exposure masks) to provide complete spatial filtering capabilities. The capabilities of the region filtering scheme are described. It also discusses the design philosophy guiding our work, as well as our plans for the future.

MANAGING AN ARCHIVE OF WEATHER SATELLITE IMAGES Abstract Only **c82**

R. L. Seaman *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 94 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The author's experiences of building and maintaining an archive of hourly weather satellite pictures at NOAO are described. This archive has proven very popular with visiting and staff astronomers - especially on windy days and cloudy nights. Given access to a source of such pictures, a suite of simple shell and IRAF CL scripts can provide a great deal of robust functionality with little effort. These pictures and associated data products such as surface analysis (radar) maps and National Weather Service forecasts are updated hourly at anonymous ftp sites on the Internet, although your local Atsmospheric Sciences Department may prove to be a more reliable source. The raw image formats are unfamiliar to most astronomers, but reading them into IRAF is straightforward. Techniques for performing this format conversion at the host computer level are described which may prove useful for other chores. Pointers are given to sources of data and of software, including a package of example tools. These tools include shell and Perl scripts for downloading pictures, maps, and forecasts, as well as IRAF scripts and host level programs for translating the images into IRAF and GIF formats and for slicing & dicing the resulting images. Hints for displaying the images and for making hardcopies are given.

DETECTOR NOISE STATISTICS IN THE NON-LINEAR REGIME Abstract Only **c32**

P. L. Shopbell and J. Bland-Hawthorn *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 95 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The statistical behavior of an idealized linear detector in the presence

of threshold and saturation levels is examined. It is assumed that the noise is governed by the statistical fluctuations in the number of photons emitted by the source during an exposure. Since physical detectors cannot have infinite dynamic range, our model illustrates that all devices have non-linear regimes, particularly at high count rates. The primary effect is a decrease in the statistical variance about the mean signal due to a portion of the expected noise distribution being removed via clipping. Higher order statistical moments are also examined, in particular, skewness and kurtosis. In principle, the expected distortion in the detector noise characteristics can be calibrated using flatfield observations with count rates matched to the observations. For this purpose, some basic statistical methods that utilize Fourier analysis techniques are described. Author (revised)

THE IRAF FABRY-PEROT ANALYSIS PACKAGE: RING FITTING Abstract Only **c82**
P. L. Shopbell, J. Bland-Hawthorn, and G. Cecil (North Carolina Univ., Chapel Hill.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 96 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

As introduced at ADASSI, a Fabry-Perot analysis package for IRAF is currently under development as a joint effort of ourselves and Frank Valdes of the IRAF group. Although additional portions of the package were also implemented, we report primarily on the development of a robust ring fitting task, useful for fitting the calibration rings obtained in Fabry-Perot observations. The general equation of an ellipse is fit to the shape of the rings, providing information on ring center, ellipticity, and position angle. Such parameters provide valuable information on the wavelength response of the etalon and the geometric stability of the system. Appropriate statistical weighting is applied to the pixels to account for increasing numbers with radius, the Lorentzian cross-section, and uneven illumination. The major problems of incomplete, non-uniform, and multiple rings are addressed with the final task capable of fitting rings regardless of center, cross-section, or completion. The task requires only minimal user intervention, allowing large numbers of rings to be fit in an extremely automated manner.

THE EVOLUTION OF THE FIGARO DATA REDUCTION SYSTEM Abstract Only **c82**
K. Shortridge *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 97 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The Figaro data reduction system originated at Caltech around 1983. It was based on concepts being developed in the U.K. by the Starlink organization, particularly the use of hierarchical self-defining data structures and the abstraction of most user-interaction into a set of 'parameter system' routines. Since 1984 it has continued to be developed at AAO, in collaboration with Starlink and Caltech. It was adopted as Starlink's main spectroscopic data reduction package, although it is by no means limited to spectra; it has operations for images and data cubes and even a few (very specialized) for four-dimensional data hypercubes. It continued to be used at Caltech and will be used at the Keck. It is also in use at a variety of other organizations around the world. Figaro was originally a system for VMS Vaxes. Recently it was ported (at Caltech) to run on SUN's, and work is underway at the University of New South Wales on a DecStation version. It is hoped to coordinate all this work into a unified release, but coordination of the development of a system by organizations covering three continents poses a number of interesting administrative problems. The hierarchical data structures used by Figaro allow it to handle a variety of types of data, and to add new items to data structures. Error and data quality information was added to the basic file format used, error information being particularly useful for infrared data. Cooperating sets of programs can add specific sub-structures to data files to carry information that they understand (polarimetry data containing multiple data arrays, for example), without this affecting the way other programs handle the files. Complex instrument-specific ancillary information can be added to data files written at a telescope and can be used by programs that understand the instrumental details in order to produce properly calibrated data files. Once this preliminary data processing was done the resulting files contain 'ordinary' spectra or images that can be processed by programs that are not instrument-specific. The structures holding the instrumental information can then be discarded from the files. Much effort has gone into trying to make it easy to write Figaro programs; data access subroutines are now available to handle access to all the conventional items found in Figaro files (main data arrays, error information, quality information etc), and programs that only need to access such items can be very simple indeed. A large number of Figaro users do indeed write their own Figaro applications using these routines. The fact that Figaro programs are written as callable subroutines getting information from the user through a small set of parameter routines means that they can be invoked in numerous ways; they are normally linked and run as individual programs (called by a small main routine that is generated automatically), but are also available linked to run under the ADAM data acquisition system and there is an interface that lets them be called as part of a user-written Fortran program. The long-term future of Figaro probably depends to a large extent on how successfully it manages the transition from being a VMS-only system to being a multi-platform system. Author (revised)

THE DATA ACQUISITION SYSTEM FOR THE ANGLO-AUSTRALIAN OBSERVATORY 2-DEGREE FIELD PROJECT Abstract Only **c82**
K. Shortridge, T. J. Farrell, and J. Bailey *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 98 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The Anglo-Australian Observatory (AAO) is building a system that will provide a two-degree field of view at prime focus. A robot positioner will be used to locate up to 400 optical fibers at pre-determined positions in this field. While observations are being made using one set of 400 fibers, the robot will be positioning a second set of fibers in a background field that can be moved in to replace the first when the telescope is moved to a new position. The fibers feed two spectrographs each with a 1024 square CCD detector. The software system being produced to control this involves Vaxes for overall control and data recording, UNIX workstations for fiber configuration calculations and on-line data reduction, and VME systems running VxWorks for real-time control of critical parts such as the positioner robot. The system has to be able to interact with the observatory's present data acquisition systems, which use the ADAM system. As yet, the real-time parts of ADAM have not been ported to Unix, and so we are having to produce a smaller-scale system that is similar but inherently distributed (which ADAM is not). We are using this system as a testbed for ideas that we hope may eventually influence an ADAM II system. The system we are producing is based on a message system that is designed to be able to handle inter-process and inter-processor messages of any length, efficiently, and without ever requiring a task to block (i.e., be unresponsive to 'cancel' messages, enquiry messages), other than when deliberately waiting for external input - all of which will be through such messages. The essential requirement is that a message 'send' operation should never be able to block. The messages will be hierarchical, self-defining, machine-independent data structures. This allows us to provide very simple monitoring of messages for diagnostic purposes, and allows general purpose interface programs to be written without needing to share precise byte by byte message format definitions. Programs in this system have interfaces defined simply in terms of named actions and their parameters. Real-time control programs are required to be able to handle a number of such actions concurrently; data reduction programs will normally only need to handle one action at a time ('process an image', 'display a spectrum', etc). INTEGRATING A LOCAL DATABASE INTO THE StarView DISTRIBUTED USER INTERFACE Abstract Only **c82**
D. P. Silberberg *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 99 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

A distributed user interface to the Space Telescope Data Archive and Distribution Service (DADS) known as StarView is being developed. The DADS architecture consists of the data archive as well as a relational database catalog describing the archive. StarView is a client/server system in which the user interface is the front-end client to the DADS catalog and

archive servers. Users query the DADS catalog from the StarView interface. Query commands are transmitted via a network and evaluated by the database. The results are returned via the network and are displayed on StarView forms. Based on the results, users decide which data sets to retrieve from the DADS archive. Archive requests are packaged by StarView and sent to DADS, which returns the requested data sets to the users. The advantages of distributed client/server user interfaces over traditional one-machine systems are well known. Since users run software on machines separate from the database, the overall client response time is much faster. Also, since the server is free to process only database requests, the database response time is much faster. Disadvantages inherent in this architecture are slow overall database access time due to the network delays, lack of a 'get previous row' command, and that refinements of a previously issued query must be submitted to the database server, even though the domain of values have already been returned by the previous query. This architecture also does not allow users to cross correlate DADS catalog data with other catalogs. Clearly, a distributed user interface would be more powerful if it overcame these disadvantages. A local database is being integrated into StarView to overcome these disadvantages. When a query is made through a StarView form, which is often composed of fields from multiple tables, it is translated to an SQL query and issued to the DADS catalog. At the same time, a local database table is created to contain the resulting rows of the query. The returned rows are displayed on the form as well as inserted into the local database table. Identical results are produced by reissuing the query to either the DADS catalog or to the local table. Relational databases do not provide a 'get previous row' function because of the inherent complexity of retrieving previous rows of multiple-table joins. However, since this function is easily implemented on a single table, StarView uses the local table to retrieve the previous row. Also, StarView issues subsequent query refinements to the local table instead of the DADS catalog, eliminating the network transmission overhead. Finally, other catalogs can be imported into the local database for cross correlation with local tables. Overall, it is believe that this is a more powerful architecture for distributed, database user interfaces. Author (revised)

A NEW PROGRAMMING METAPHOR FOR IMAGE PROCESSING PROCEDURES Abstract Only **c61**

O. M. Smirnov and N. E. Piskunov (Helsinki Univ., Finland.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 100 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Most image processing systems, besides an Application Program Interface (API) which lets users write their own image processing programs, also feature a higher level of programmability. Traditionally, this is a command or macro language, which can be used to build large procedures (scripts) out of simple programs or commands. This approach, a legacy of the teletypewriter has serious drawbacks. A command language is clumsy when (and if) it attempts to utilize the capabilities of a multitasking or multiprocessor environment, it is but adequate for real-time data acquisition and processing, it has a fairly steep learning curve, and the user interface is very inefficient,. especially when compared to a graphical user interface (GUI) that systems running under XII or Windows should otherwise be able to provide. II these difficulties stem from one basic problem: a command language is not a natural metaphor for an image processing procedure. A more natural metaphor - an image processing factory is described in detail. A factory is a set of programs (applications) that execute separate operations on images, connected by pipes that carry data (images and parameters) between them. The programs function concurrently, processing images as they arrive along pipes, and querying the user for whatever other input they need. From the user's point of view, programming (constructing) factories is a lot like playing with LEGO blocks - much more intuitive than writing scripts. Focus is on some of the difficulties of implementing factory support, most notably the design of an appropriate API. It also shows that factories retain all the functionality of a command language (including loops and conditional branches), while suffering from none of the drawbacks outlined above. Other benefits of factory programming include self-tuning factories and the process of encapsulation, which lets a factory take the shape of a standard application both from the system and the user's point of view, and thus be used as a component of other factories. A bare-bones prototype of factory programming was implemented under the PcIPS image processing system, and a complete version (on a multitasking platform) is under development. Author (revised)

PCIPS 2.0: POWERFUL MULTIPROFILE IMAGE PROCESSING IMPLEMENTED ON PCs Abstract Only **c61**

O. M. Smirnov and N. E. Piskunov (Helsinki Univ., Finland.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 101 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

Over the years, the processing power of personal computers has steadily increased. Now, 386- and 486-based PC's are fast enough for many image processing applications, and inexpensive enough even for amateur astronomers. PCIPS is an image processing system based on these platforms that was designed to satisfy a broad range of data analysis needs, while requiring minimum hardware and providing maximum expandability. It will run (albeit at a slow pace) even on a 80286 with 640K memory, but will take full advantage of bigger memory and faster CPU's. Because the actual image processing is performed by external modules, the system can be easily upgraded by the user for all sorts of scientific data analysis. PCIPS supports large format ID and 2D images in any numeric type from 8-bit integer to 64-bit floating point. The images can be displayed, overlaid, printed and any part of the data examined via an intuitive graphical user interface that employs buttons, pop-up menus, and a mouse. PCIPS automatically converts images between different types and sizes to satisfy the requirements of various applications. PCIPS features an API that lets users develop custom applications in C or FORTRAN. While doing so, a programmer can concentrate on the actual data processing, because PCIPS assumes responsibility for accessing images and interacting with the user. This also ensures that all applications, even custom ones, have a consistent and user-friendly interface. The API is compatible with factory programming, a metaphor for constructing image processing procedures that will be implemented in future versions of the system. Several application packages were created under PCIPS. The basic package includes elementary arithmetics and statistics, geometric transformations and import/export in various formats (FITS, binary, ASCII, and GIF). The CCD processing package and the spectral analysis package were successfully used to reduce spectra from the Nordic Telescope at La Palma. A photometry package is also available, and other packages are being developed. A multitasking version of PCIPS that utilizes the factory programming concept is currently under development. This version will remain compatible (on the source code level) with existing application packages and custom applications. Author (revised)

GUIDE STAR CATALOGUE DATA RETRIEVAL SOFTWARE 2 Abstract Only **c61**

O. M. Smirnov and O. Yu. Malkov *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 102 (For primary document see N94-22438 05-89)

Avail: CASI HC A01/MF A02

The Guide Star Catalog (GSC), being the largest astronomical catalog to date, is widely used by the astronomical community for all sorts of applications, such as statistical studies of certain sky regions, searches for counterparts to observational phenomena, and generation of finder charts. It's format (2 CD-ROM's) requires minimum hardware and is ideally suited for all sorts of conditions, especially observations. Unfortunately, the actual GSC data is not easily accessible. It takes the form of FITS tables, and the coordinates of the objects are given in one coordinate system (equinox 2000). The included reading software is rudimentary at best. Thus, even generation of a simple finder chart is not a trivial undertaking. To solve this problem, at least for PC users, GUIDARES was created. GUIDARES is a user-friendly program that lets you look directly at the data in the GSC, either as a graphical sky map or as a text table. GUIDARES can read a sampling of GSC data from a given sky region, store this sampling in a text file, and display a graphical map of the sampled region in

projected celestial coordinates (perfect for finder charts). GUIDARES supports rectangular and circular regions defined by coordinates in the equatorial, ecliptic (any equinox) or galactic systems. Author (revised)

UIT SUPPORT OBSERVATIONS ARCHIVE Abstract Only c82
Eric P. Smith, Paul Hintzen, and Kwang-Ping Cheng *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 103 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

We are in the process of archiving the approximately 1.2Tbytes of imaging data acquired in support of UIT observations. The UIT is one of three telescopes comprising the ASTRO spacecraft and is a 38-cm f/9 Ritchey-Chretien telescope with wavelength coverage 1200 A to 3000 A and a 40 arcminute diameter field-of-view at 4 min FWHM resolution. During the ASTRO shuttle mission, there were 65 different pointings (some with multiple targets) of the UIT and hence 65 fields. Our support data of these fields were obtained with the KPNO and CTIO 0.9m telescopes and several of the 2048x2048 CCD's. Our images are typically about 20 acrminutes on a side and contain the entire UV target except for nearby galaxies, for which mosaiced images were created. All good quality images in the broadband and narrow band filters for every target are being archived. Though all of the UIT targets were well studied astronomical objects, these frames are many of the first large field format images of them and, when combined with the soon to be released UV frames, provide a unique dataset. These data were already used to address a wide variety of astronomical questions. Vacuum ultraviolet (VUV) observations were used to study star formation in a sample of nearby galaxies, since integrated VUV - optical colors provide the most sensitive available measure of the formation rate of massive stars. The blue stages later in stellar evolution are also being studied. These data allow more accurate determination of the helium and metallicities of hothorzontal branch stars. These data are being prepared to release to the public in CD-ROM format through the National Space Science Data Center. Author (revised)

IRAF IN THE NINETIES Abstract Only c82
D. Tody *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 104 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The Interactive Data Reduction and Analysis Facility (IRAF) data reduction and analysis system has been around since 1981. Today it is a mature system with hundreds of applications, and is supported on all the major platforms. Many institutions, projects, and individuals around the US and around the world have developed software for IRAF. Some of these packages are comparable in size to the IRAF core system itself. IRAF is both a data analysis system, and a programming environment. As a data analysis system it can be easily installed by a user at a remote site and immediately used to view and process data. As a programming environment IRAF contains a wealth of high and low level facilities for developing new applications for interactive and automated processing of astronomical or other data. As important as the applications programs and user interfaces are to the scientist using IRAF, the heart of the IRAF system is the programming environment. The programming environment determines to a large extent the types of applications which can be built within IRAF, what they will look like, and how they will interact with one another and with the user. While applications can be easily added to or removed from a software system, the programming environment must remain fairly stable, with carefully planned evolution and growth, over the lifetime of a system. The IRAF programming environment is the framework on which the rest of the IRAF system is built. The IRAF programming environment as it exists in 1992, and the work currently underway to enhance the environment are discussed. The structure of the programming environment as a class hierarchy is discussed, with emphasis on the work being done on the image data structures, graphics and image display interfaces, and user interfaces. The new technologies which we feel IRAF must deal with successfully over the coming years are discussed. Finally, a preview of what IRAF might look like to the user by the end of the decade is presented. Author (revised)

FACTOR ANALYSIS AS A TOOL FOR SPECTRAL LINE COMPONENT SEPARATION 21cm EMISSION IN THE DIRECTION OF L1780 Abstract Only c65
L. V. Toth, K. Mattila, L. Haikala, and L. G. Balazs (Konkoly Observatory, Budapest, Hungary.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 105 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The spectra of the 21cm HI radiation from the direction of L1780, a small high-galactic latitude dark/molecular cloud, were analyzed by multivariate methods. Factor analysis was performed on HI (21cm) spectra in order to separate the different components responsible for the spectral features. The rotated, orthogonal factors explain the spectra as a sum of radiation from the background (an extended HI emission layer), and from the L1780 dark cloud. The coefficients of the cloud-indicator factors were used to locate the HI 'halo' of the molecular cloud. Our statistically derived 'background' and 'cloud' spectral profiles, as well as the spatial distribution of the HI halo emission distribution were compared to the results of a previous study which used conventional methods analyzing nearly the same data set. RECOMMENDATIONS FOR A SERVICE FRAMEWORK TO ACCESS ASTRONOMICAL ARCHIVES Abstract Only c82
J. J. Travisano and J. Pollizzi (Space Telescope Science Inst., Baltimore, MD.) *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 106 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

There are a large number of astronomical archives and catalogs on-line for network access, with many different user interfaces and features. Some systems are moving towards distributed access, supplying users with client software for their home sites which connects to servers at the archive site. Many of the issues involved in defining a standard framework of services that archive/catalog suppliers can use to achieve a basic level of interoperability are described. Such a framework would simplify the development of client and server programs to access the wide variety of astronomical archive systems. The primary services that are supplied by current systems include: catalog browsing, dataset retrieval, name resolution, and data analysis. The following issues (and probably more) need to be considered in establishing a standard set of client/server interfaces and protocols: Archive Access - dataset retrieval, delivery, file formats, data browsing, analysis, etc.; Catalog Access - database management systems, query languages, data formats, synchronous/asynchronous mode of operation, etc.; Interoperability - transaction/message protocols, distributed processing mechanisms (DCE, ONC/SunRPC, etc), networking protocols, etc.; Security - user registration, authorization/authentication mechanisms, etc.; Service Directory - service registration, lookup, port/task mapping, parameters, etc.; Software - public vs proprietary, client/server software, standard interfaces to client/server functions, software distribution, operating system portability, data portability, etc. Several archive/catalog groups, notably the Astrophysics Data System (ADS), are already working in many of these areas. In the process of developing StarView, which is the user interface to the Space Telescope Data Archive and Distribution Service (ST-DADS), these issues and the work of others were analyzed. A framework of standard interfaces for accessing services on any archive system which would benefit archive user and supplier alike is proposed.

THE SPECTRAL WORLD COORDINATE SYSTEMS IN IRAF/NOAO Abstract Only **c82**
F. Valdes *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 108 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The world coordinate system (WCS) for dispersion calibrated spectra used in the IRAF/NOAO spectroscopy packages is described. In particular, the image header keywords which define the coordinates in an 'image' pixel array. These keywords appear both as part of the IRAF image structure and map directly to FITS format. The types of spectra include multidimensional images with spectral dispersion as one axis, one dimensional images, and a special 'multispec' format consisting of multiple, semi-independent, one dimensional spectra in two or three dimensional images. The types of coordinate systems include multidimensional linear coordinates with individual keywords and one dimensional linear and nonlinear coordinates for the 'multispec' images stored in IRAF WCS attributes. The nonlinear world coordinate systems include polynomial, spline, sampled table, and look-up table function representations. Author

SPECFOCUS: AN IRAF TASK FOR FOCUSING SPECTROGRAPHS Abstract Only **c65**
F. Valdes *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 109 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

An IRAF task for measuring the point-spread function (PSF) along the dispersion and wavelength shifts across the dispersion in two dimensional arc spectra is described. In typical use, a set of spectra are obtained with various spectrograph focusing and alignment adjustments and the PSF information and shift information is derived and presented in tabular and graphical forms. Within each image the spectra may be divided into a number of samples along the dispersion and across the dispersion to investigate variations at different points in the detector at fixed focus settings. With many spectra and many samples interpreting the measurements is challenging. The task provides an interactive graphical interface to display the measurements in a number of interesting ways. The underlying algorithm for measuring the PSF and shifts in the auto/cross-correlation of spectral are samples. Author

NASA maintains an archive facility for Astronomical Science data collected from NASA's missions at the National Space Science Data Center (NSSDC) at Goddard Space Flight Center. This archive was created to insure the science data collected by NASA would be preserved and useable in the future by the science community. Through 25 years of operation there are many lessons learned, from data collection procedures, archive preservation methods, and distribution to the community. This document presents some of these more important lessons, for example: KISS (Keep It Simple, Stupid) in system development. Also addressed are some of the myths of archiving, such as 'scientists always know everything about everything', or 'it cannot possibly be that hard, after all simple data tech's do it'. There are indeed good reasons that a proper archive capability is needed by the astronomical community, the important question is how to use the existing expertise as well as the new innovative ideas to do the best job archiving this valuable science data. DECONV-TOOL: AN IDL BASED DECONVOLUTION SOFTWARE PACKAGE Abstract only **c61**
F. Varosi and W. B. Landsman *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 111 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

There are a variety of algorithms for deconvolution of blurred images, each having its own criteria or statistic to be optimized in order to estimate the original image data. Using the Interactive Data Language (IDL), we have implemented the Maximum Likelihood, Maximum Entropy, Maximum Residual Likelihood, and sigma-CLEAN algorithms in a unified environment called DeConv—Tool. Most of the algorithms have as their goal the optimization of statistics such as standard deviation and mean of residuals. Shannon entropy, log-likelihood, and chi-square of the residual auto-correlation are computed by DeConv—Tool for the purpose of determining the performance and convergence of any particular method and comparisons between methods. DeConv—Tool allows interactive monitoring of the statistics and the deconvolved image during computation. The final results, and optionally, the intermediate results, are stored in a structure convenient for comparison between methods and review of the deconvolution computation. The routines comprising DeConv—Tool are available via anonymous FTP through the IDL Astronomy User's Library. Author

MOSAIC: SOFTWARE FOR CREATING MOSAICS FROM COLLECTIONS OF IMAGES Abstract Only **c61**
F. Varosi and D. Y. Gezari *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 112 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

We have developed a powerful, versatile image processing and analysis software package called MOSAIC, designed specifically for the manipulation of digital astronomical image data obtained with (but not limited to) two-dimensional array detectors. The software package is implemented using the Interactive Data Language (IDL), and incorporates new methods for processing, calibration, analysis, and visualization of astronomical image data, stressing effective methods for the creation of mosaic images from collections of individual exposures, while at the same time preserving the photometric integrity of the original data. Since IDL is available on many computers, the MOSAIC software runs on most UNIX and VAX workstations with the X-Windows or Sun View graphics interface. Author

STELAR: AN EXPERIMENT IN THE ELECTRONIC DISTRIBUTION OF ASTRONOMICAL LITERATURE Abstract Only **c82**
A. Warnock, M. E. VanSteenburg (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.), L. E. Brotzman, J. Gass, and D. Kovalsky *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 113 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

STELAR (Study of Electronic Literature for Astronomical Research) is a Goddard-based project designed to test methods of delivering technical literature in machine readable form. To that end, we have scanned a five year span of the ApJ, ApJ Supp, AJ and PASP, and have obtained abstracts for eight leading academic journals from NASA/STI CASI, which also makes these abstracts available through the NASA RECON system. We have also obtained machine readable versions of some journal volumes from the publishers, although in many instances, the final typeset versions are no longer available. The fundamental data object for the STELAR database is the article, a collection of items associated with a scientific paper - abstract, scanned pages (in a variety of formats), figures, OCR extractions, forward and backward references, errata and versions of the paper in various formats (e.g., TEX, SGML, PostScript, DVI). Articles are uniquely referenced in the database by journal name, volume number and page number. The selection and delivery of articles is accomplished through the WAIS (Wide Area Information Server) client/server models requiring only an Internet connection. Modest modifications to the server code have made it capable of delivering the multiple data types required by STELAR.

WAIS is a platform independent and fully open multi-disciplinary delivery system, originally developed by Thinking Machines Corp. and made available free of charge. It is based on the ISO Z39.50 standard communications protocol. WAIS servers run under both UNIX and VMS. WAIS clients run on a wide variety of machines, from UNIX-based Xwindows systems to MS-DOS and macintosh microcomputers. The WAIS system includes full-test indexing and searching of documents, network interface and easy access to a variety of document viewers. ASCII versions of the CASI abstracts have been formatted for display and the full test of the abstracts has been indexed. The entire WAIS database of abstracts is now available for use by the astronomical community. Enhancements of the search and retrieval system are under investigation to include specialized searches (by reference, author or keyword, as opposed to full test searches), improved handling of word stems, improvements in relevancy criteria and other retrieval techniques, such as factor spaces. The STELAR project has been assisted by the full cooperation of the AAS, the ASP, the publishers of the academic journals, librarians from GSFC, NRAO and STScI, the Library of Congress, and the University of North Carolina at Chapel Hill. SkICAT: A CATALOGING AND ANALYSIS TOOL FOR WIDE FIELD IMAGING SURVEYS Abstract Only **c82**
N. Weir (California Inst. of Tech., Pasadena.), U. M. Fayyad, S. G. Djorgovski (California Inst. of Tech., Pasadena.), and J. Roden *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 115 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

We describe an integrated system, SkICAT (Sky Image Cataloging and Analysis Tool), for the automated reduction and analysis of the Palomar Observatory-ST ScI Digitized Sky Survey. The Survey will consist of the complete digitization of the photographic Second Palomar Observatory Sky Survey (POSS-II) in three bands, comprising nearly three Terabytes of pixel data. SkICAT applies a combination of existing packages, including FOCAS for basic image detection and measurement and SAS for database management, as well as custom software, to the task of managing this wealth of data. One of the most novel aspects of the system is its method of object classification. Using state-of-theart machine learning classification techniques (GID3* and O-BTree), we have developed a powerful method for automatically distinguishing point sources from non-point sources and artifacts, achieving comparably accurate discrimination a full magnitude fainter than in previous Schmidt plate surveys. The learning algorithms produce decision trees for classification by examining instances of objects classified by eye on both plate and higher quality CCD data. The same techniques will be applied to perform higher-level object classification (e.g., of galaxy morphology) in the near future. Another key feature of the system is the facility to integrate the catalogs from multiple plates (and portions thereof) to construct a single catalog of uniform calibration and quality down to the faintest limits of the survey. SkICAT also provides a variety of data analysis and exploration tools for the scientific utilization of the resulting catalogs. We include initial results of applying this system to measure the counts and distribution of galaxies in two bands down to Bj is approximately 21 mag over an approximate 70 square degree multi-plate field from POSS-II. SkICAT is constructed in a modular and general fashion and should be readily adaptable to other large-scale imaging surveys. Author (revised)

THE VLBA CORRELATOR: REAL-TIME IN THE DISTRIBUTED ERA Abstract Only **c82**
D. C. Wells *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 116 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The correlator is the signal processing engine of the Very Long Baseline Array (VLBA). Radio signals are recorded on special wideband (128 Mb/s) digital recorders at the 10 telescopes, with sampling times controlled by hydrogen maser clocks. The magnetic tapes are shipped to the Array Operations Center in Socorro, New Mexico, where they are played back simultaneously into the correlator. Real-time software and firmware controls the playback drives to achieve synchronization, compute models of the wavefront delay, control the numerous modules of the correlator, and record FITS files of the fringe visibilities at the back-end of the correlator. In addition to the more than 3000 custom VLSI chips which handle the massive data flow of the signal processing, the correlator contains a total of more than 100 programmable computers, 8-, 16- and 32-bit CPUs. Code is downloaded into front-end CPU's dependent on operating mode. Low-level code is assembly language, high-level code is C running under a RT OS. We use VxWorks on Motorola MVME147 CPU's. Code development is on a complex of SPARC workstations connected to the RT CPU's by Ethernet. The overall management of the correlation process is dependent on a database management system. We use Ingres running on a Sparcstation-2. We transfer logging information from the database of the VLBA Monitor and Control System to our database using Ingres/NET. Job scripts are computed and are transferred to the real-time computers using NFS, and correlation job execution logs and status flow back by the route. Operator status and control displays use windows on workstations, interfaced to the real-time processes by network protocols. The extensive network protocol support provided by VxWorks is invaluable. The VLBA Correlator's dependence on network protocols is an example of the radical transformation of the real-time world over the past five years. Real-time is becoming more like conventional computing. Paradoxically, 'conventional' computing is also adopting practices from the real-time world: semaphores, shared memory, light-weight threads, and concurrency. This appears to be a convergence of thinking. Author

StarView: THE OBJECT ORIENTED DESIGN OF THE ST DADS USER INTERFACE Abstract Only **c82**
J. D. Williams and J. A. Pollizzi *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 117 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

StarView is the user interface being developed for the Hubble Space Telescope Data Archive and Distribution Service (ST DADS). ST DADS is the data archive for HST observations and a relational database catalog describing the archived data. Users will use StarView to query the catalog and select appropriate datasets for study. StarView sends requests for archived datasets to ST DADS which processes the requests and returns the database to the user. StarView is designed to be a powerful and extensible user interface. Unique features include an internal relational database to navigate query results, a form definition language that will work with both CRT and X interfaces, a data definition language that will allow StarView to work with any relational database, and the ability to generate adhoc queries without requiring the user to understand the structure of the ST DADS catalog. Ultimately, StarView will allow the user to refine queries in the local database for improved performance and merge in data from external sources for correlation with other query results. The user will be able to create a query from single or multiple forms, merging the selected attributes into a single query. Arbitrary selection of attributes for querying is supported. The user will be able to select how query results are viewed. A standard form or table-row format may be used. Navigation capabilities are provided to aid the user in viewing query results. Object oriented analysis and design techniques were used in the design of StarView to support the mechanisms and concepts required to implement these features. One such mechanism is the Model-View-Controller (MVC) paradigm. The MVC allows the user to have multiple views of the underlying database, while providing a consistent mechanism for interaction regardless of the

view. This approach supports both CRT and X interfaces while providing a common mode of user interaction. Another powerful abstraction is the concept of a Query Model. This concept allows a single query to be built form a single or multiple forms before it is submitted to ST DADS. Supporting this concept is the adhoc query generator which allows the user to select and qualify an indeterminate number attributes from the database. The user does not need any knowledge of how the joins across various tables are to be resolved. The adhoc generator calculates the joins automatically and generates the correct SQL query. TESTS OF A SIMPLE DATA MERGING ALGORITHM FOR THE GONG PROJECT Abstract Only **c61**
W. E. Williams and F. Hill *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 118 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The GONG (Global Oscillation Network Group) project proposes to reduce the impact of diurnal variations on helioseismic measurements by making long-term observations of solar images from six sites placed around the globe. The sun will be observed nearly constantly for three years, resulting in the acquisition of l+ terabyte of image data. To use the solar network to maximum advantage, the images from the sites must be combined into a single time series to determine mode frequencies, amplitudes, and line widths. Initial versions of combined, i.e., merged, time series were made using a simple weighted average of data from different sites taken simultaneously. In order to accurately assess the impact of the data merge on the helioseismic measurements, a set of artificial solar disk images was made using a standard solar model and containing a well known set of oscillation modes and frequencies. This undegraded data set and data products computed from it were used to judge the relative merits of various data merging schemes. The artificial solar disk images were subjected to various instrumental and atmospheric degradations, dependent on site and time, in order to create a set of images simulating those likely to be taken at the site. The degraded artificial solar disk images for the six observing sites were combined in various ways to form merged time series of images and mode coefficients. Various forms of a weighted average were used, including an equally-weighted average, an average with weights dependent upon air mass and averages with weights dependent on various quality assurance parameters. Both the undegraded solar disk image time series and several time series made up of various combinations of the degraded solar disk images from the six sites were subjected to standard helioseismic measurement processing. This processing consisted of coordinate remapping, detrending, spherical harmonic transformation, computation of power series for the oscillation mode coefficients, and mode frequency identification. Visual and statistical evaluation of the merged data sets themselves and differences between the merged and undegraded data set shows good agreement between the two data sets. Some slight differences in image scale and registration appear between the undegraded data set and the various merged data sets. In the set of power series made from the mode coefficients of the merged data sets, some power leakage is observed into the background and into slightly lower l-value modes, especially at higher l-value mode frequencies. The results of the comparison of time series and mode oscillation frequencies of the undegraded data with those of the data merged using weighted averages indicate that, at least for p-mode solar oscillations, a weighted average of either the detrended remapped images or the mode coefficients gives good determination of the mode frequencies and adequate-to-good determination of the amplitudes and widths of the mode frequency lines. This conclusion is most advantageous to the analysis of the massive amounts of data to be received by the GONG network. Author (revised)

REGISTERING AND RESAMPLING IMAGES IN STSDAS Abstract Only **c61**
R. L. Williamson, II *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 119 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

Registering different images can be difficult, especially if the images to be registered are images at different wavelengths, where features in one image may look entirely different or be absent from the second image. Using two new packages soon to be added to the STSDAS package, REGISTER and RESAMPLE, this job is done automatically. The REGISTER package allows the user to determine the amount of translation, rotation, and/or magnification needed to make two images, spectra, or time series congruent. The methods implemented to compute the registration parameters use: a set of the pixel coordinates of the same features identified in two files, or the FITS coordinate transformation parameters in the headers of two data files, or a single feature identified as the peak of a cross-correlation between two vectors. The coefficients describing the registration are defined by the equations (for a two-dimensional image): $x = a + bx + cy$, $y = d + ex + fy$, where (X,Y) are the pixel coordinates of a feature in the reference image, (x,y) are the pixel coordinates of a feature in the secondary image, and the computed coefficients are a, b, c, d, e, and f. Results may be produced by linking the output of REGISTER to RESAMPLE in a command language procedure. The output from REGISTER and the input to RESAMPLE consists of a matrix of coefficients (a through f above) fully specifying the registration. The RESAMPLE package resamples simple vector or image data for a given amount of translation, rotation (images only), and magnification, or reflection of the science data. Specific options included are: image rotation about the FITS reference pixel; scale changes, i.e. magnification or demagnification (for images, independently on both axes); simple translation; reflection (for images, about one or both axes); and resampling and registration to a reference data set. Output from the RESAMPLE task is the resampled image which may then be displayed and compared with the reference image. Author (revised)

FIRST MEM TASK IRMEO IN IRAF Abstract Only **c61**
Nailong Wu *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 120 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

The first task for image restoration using the Maximum Entropy Method (MEM) in IRAF, called IRMEO, is described. The underlining algorithm is the approximate Newton method for optimization. The basic input images and parameters for deconvolution are described in some detail. Results of preliminary tests, including the number of iterations, required CPU time on a variety of computers, and deconvolved images are reported and compared with those from other deconvolution methods. The merits and limitations of this task are pointed out. The possible development of better MEM tasks on the basis of IRMEO is also discussed. Author

The paper introduces terminal hardware system of 10 cm high resolution full-disk magnetic field telescope among solar multi-channel telescope produced by Beijing Astronomical Observatory, and its software procedure by using imaging processing as well real time data collecting. These data were processed by Sun Workstation 470/4, including doing some spectrum analysis, the system is unique in the world now. It uses a set of CCD (1320 pixels plus 1035 pixels) of high resolution image explosion, also it has a set of fast and high resolution (1024 pixel plus 1024 pixel) image processor. Moreover, we can obtain higher time and space resolution about solar full-disk magnetic field and velocity field. This will provide excellent means in observation and studies of full-disk solar large-scale magnetic field and velocity field. Author

Digital's next generation RISC architecture, known as ALPHA, presents

many IRAF system portability questions and challenges to both site managers and end users. DEC promises to support the ULTRIX, VMS, and OSF/1 operating systems, which should allow IRAF to be ported to the new architecture at either the program executable level (using VEST), or at the source level, where IRAF can be tuned for greater performance. These notes highlight some of the details of porting IRAF to OpenVMS on the ALPHA architecture. Author

Avail: CASI HC A01/MF A02

A new meter-wave survey of sky region north of declination +30 deg is carried out with the Miyun 232 MHz Synthesis Radio Telescope (MSRT). The instrument, observation, and method of data reduction are briefly described. A preliminary catalog, first of a series, for two 8 deg. x 8 deg. regions centered respectively at 35 deg. is presented. On the average 4 - 5 sources per square degree are recorded with position accuracy of 5 sec. / S(Jy). BGPW scale is adopted for the flux density calibration. The accuracy of flux determination is limited by background fluctuation which is about 30 mJy. The catalog is complete for sources with flux larger than 0.25 Jy. The total number of sources listed in the paper amounts to 687. Several extended sources, sources with convex spectra, and one GPS source were found. Spectra of sources with flux larger than 0.5 Jy were also given. Author

ROSAT DATA ANALYSIS WITH EXSAS Abstract Only
H. U. Zimmermann, T. Belloni, C. Izzo, P. Kahabka, and O. Schwentker *In* NASA, Washington, Second Annual Conference on Astronomical Data Analysis Software and Systems. Abstracts 1992 p 124 (For primary document see N94-22438 05-89)
Avail: CASI HC A01/MF A02

For the x-ray observatory ROSAT, data from survey and pointed mission phases taken with different focal plane instruments and according to a complex mission timeline have to be handled. Data analysis therefore puts high demands on appropriate software tools. With EXSAS - the Extended Scientific Analysis System developed with an effort of 20 man years by the German ROSAT Scientific Data Center - a comfortable system for the reduction of data from the ROSAT x-ray and XUV instruments has been made available. EXSAS comprises a large collection of application modules as typically required in analyzing data of this wavelength regime and runs as a specific context in the wide-spread ESO-MIDAS environment. EXSAS, completely written in FORTRAN 77, takes full advantage of all the standards used in MIDAS and therefore, reflects the same portability (different UNIX installations and VMS). If required, the FORTRAN code also enables users to adapt the software in an easy way to their specific needs. To maintain independence from the specifics of different operating systems also on the data input side, all ROSAT data redistributed in the widely accepted FITS format. Although EXSAS has been developed specifically for data analysis of the ROSAT instruments, its structural design is sufficiently general to serve equally well also data from other X-ray and XUV instruments. EXSAS analysis modules are grouped into 4 application packages dealing with Data Preparation and Instrument Correction, Spatial Analysis, Spectral Analysis and Timing Analysis. A special EXSAS header, read and updated by each application, maintains the general information transfer on the origin, the history and the parameter space of the data stored in tables and images. About 100 genuine commands (most of which offer several additional options) allow to interactively explore the functionality of the system. Up to now 40 institutes all over the world have requested the EXSAS software. Maintenance and regular updates of the software and the comprehensive documentation are provided by the ROSAT Scientific Data Center at Garching. Author

PRE-MAIN SEQUENCE STARS IN THE CHAMAELEON CLOUD AND PRE-MAIN SEQUENCE STARS IN THE RHO OPHIUCHI CLOUD CORE Final Report
Eric D. Feigelson 15 Dec. 1993 3 p Submitted for publication
(Grant NAG5-1678)
(NASA-CR-194713; NAS 1.26:194713) Avail: CASI HC A01/MF A01

This grant funds two closely related studies of young stars under the ROSAT Guest Observer Program. A major paper on ROSAT discovery of X-ray emitting young stars in the Chamaeleon star forming cloud was published in the Astrophysical Journal. Two soft X-ray images of the Chamaeleon I star forming cloud obtained with the ROSAT Position Sensitive Proportional Counter are presented. Seventy reliable, and 19 possible additional, X-ray sources are found. Most are confirmed to be new weak T Tauri stars. A study of X-ray emitting stars in a deep ROSAT image of the rho Ophiuchi star forming cloud cores has been completed, and is being submitted for publication in the Astrophysical Journal. A list of X-ray sources, fluxes, signal-to-noise ratios and boresight-corrected positions has been compiled, and optical identification down to 22(exp m) are obtained. Of the 55 reliable ROSAT sources, virtually all are associated with embedded infrared-detected T Tauri stars. T Tauri X-rays may provide a crucial link in the photoionization self-regulation of star formation in the galaxy.

A Fabri-Perot spectrometer for examination of astronomical objects with high spatial and spectral resolution is developed. Wide-band and circular variable filter were used for pre-decomposition. The measuring instrument was designed to be compatible with telescopes of varied aperture numbers and was equipped with a modular computer and cards for quick data transfer. The sensitivity was improved for optimization of surface detector representation methods. Results were obtained for the Seyfert-2 galaxy NGC 1068 and the Milky Way center, which supplied images of galactic nuclei in emission lines of varied atomic species. Seyfert-2 galaxy was recorded in Br-gamma recombination line of atomic hydrogen and of a quadrupole transfer of molecular hydrogen, whose emission has a cloud structure morphology. It can be concluded that galactic circumnuclear materials is aggregated in molecular clouds. A dozen compact sources were discovered in the Milky Way with broad helium emission lines. It can be deduced that luminosity is produced in galactic center through stars. ESA

The basic concept of some stationary models and the way in which these models are used for and in how far they influence the determination of stellar and wind parameters of massive hot stars are discussed. However, as follows directly from the assumption of stationarity, these models are inherently incapable of describing a number of additional observational features, which immediately show that the nonstationary aspects of the wind must be of significant importance. A number of these features are discussed: the soft X-ray emission; the discrete absorption components; the temporal variability of the wind lines, where the blue edges are varying most significantly while the red emission part remains relatively constant; the electron scattering wings of recombination lines in Wolf-Rayet stars; the black troughs in saturated P-Cygni profiles; the variability of optical lines; and the nonthermal radio emission observed in massive stars. The basic picture resulting from the present dynamical models is discussed. ESA

We overview three recently proposed sites for the formation of unstable nuclei in astrophysics. These include the development a new Urca-like process in the late stages of the evolution of massive stars; the development of unstable elements in the hot neutrino energized wind from the nascent neutron star in supernovae or gamma-ray burst models; and the formation and evolution of baryon inhomogeneities produced by cosmological phase transitions and expanded by neutrino induced heating during the big bang. In each of these environments the importance of unstable nuclei will be discussed and some useful measurements proposed. DOE

CIRCUMSTELLAR ENVIRONMENTS OF Be STARS AT INFRA-RED AND RADIO WAVELENGTHS Ph.D. Thesis
Sean Melbourne Dougherty Feb. 1993 107 p
(ISBN-0-315-83135-9; CTN-94-60937) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Circumstellar environments of Be stars are investigated via analysis of observations at near-infrared (IR) and radio wavelengths. Near-IR and quasi-simultaneous visual observations of Be and normal B-type stars were obtained. Intrinsic color relationships for B stars were derived. Excess IR emission is present for about 60% of Be stars. The excess color-color relationships are consistent with circumstellar envelopes of radius greater than 10 stellar radii and power law radial density distributions. The percentage of variable Be stars increases with wavelength, with 18% of the sample studied being identified as variables at K band. Variations are attributed to density variations in the circumstellar plasma. New multi-wavelength radio observations of six Be stars are presented, three of which appear to have variable radio emission. Emission from the Be star Psi Persei is resolved at 15 GHz. The radio emitting region has a major axis dimension of 111 milli arc seconds (mas) and the minor axis has an upper limit of 68 mas. The angular size of the major axis corresponds to a radius of 1,850 solar radii (SR). Using a radiative transfer disc model, it is shown that a truncated circumstellar disc cannot account for both the IR to radio spectrum of the excess emission and the observed radius of 1,850 SR. WHAT IS NORMAL AMONG THE A-TYPE STARS? Ph.D. Thesis
Grant Michael Hill Sep. 1993 156 p
(ISBN-0-315-83947-3; CTN-94-60962) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The abundances of 15 elements have been determined for 16 early A-type stars. Abundances were also determined for Sirius, a hot Am star, and lambda Boo, the prototypical member of its class. Spectrum synthesis was used to determine the abundances; it is shown to be reliable and capable of application to even broader lined stars. Despite the fact that 14 of the stars are classified as normal, they exhibit a considerable range of abundances. The abundances of most elements scale, at least roughly, with those of Fe, which ranges over more than 0.7 dex among supposedly normal stars. Carbon is probably anti-correlated with Fe while Ca exhibits a more complex behavior. Helium seems constant and slightly under-abundant with respect to the sun. Elements heavier than Fe generally show an enhancement with respect to the sun. Correlations of the abundances with various stellar parameters are studied. For some elements, such as Fe, the average abundance is roughly solar; for others, such as the heavy elements, it is not. The range of abundances exhibited by most elements is wide enough that there seems to be a continuous distribution of abundances from those of the Am stars through the normal stars. The lambda Boo stars may be the low abundance tail of this distribution. Author (CISTI)

Pre-main sequence evolutionary tracks have been calculated for a series of massive star models under Hayashi's canonical theory and Stahler's mass accretion paradigm. Canonical pre-main sequence tracks for 15-60 solar mass (SM) stars were calculated with both Cox-Stewart (CS) and Rogers-Iglesias (RI) opacities. The differences between the two sequences were systematically explored. The final pre-main sequence phase of the canonical evolution and the onset of central hydrogen burning is discussed. Arrival of a massive star on the zero age main sequence (ZAMS) is defined and the characteristics of the upper ZAMS models are determined. A systematic investigation of pre-main sequence tracks revealed a boundary in the central density versus central temperature plane, beyond which the models always had a central convective core. In a study of a sequence of accretion models, beyond about 17 SM their characteristics became increasingly more luminous and cooler compared to the same-mass canonical ZAMS models. In the main sequence phase, the accretion build model evolved at essentially the same effective temperature as the canonical model but at a lower luminosity. An upper stellar birthline is proposed, defining a boundary in the Hertzsprung Russell diagram beyond which massive stars first become optically visible. Author (CISTI)

N94-20704*# Naturhistorisches Museum, Vienna (Austria).
ELEMENTAL DEPLETIONS IN ANTARCTIC MICROMETEORITES AND ARCTIC COSMIC SPHERULES: COMPARISON AND RELATIONSHIPS Abstract Only

T. Presper, G. Kurat, C. Koeberl (Wien Univ., Austria.), H. Palme (Max-Planck-Inst. fuer Chemie, Mainz, Germany.), and Michel Maurette (Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Orsay, France.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1177-1178 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20708*# American Museum of Natural History, New York, NY. Dept. of Mineral Science.
OXYGEN ISOTOPIC RELATIONSHIPS BETWEEN THE LEW85332 CARBONACEOUS CHONDRITE AND CR CHONDRITES Abstract Only
M. Prinz, M. K. Weisberg, R. N. Clayton (Chicago Univ., IL), and T. K. Mayeda (Chicago Univ., IL.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1185-1186 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20715*# New Mexico Univ., Albuquerque. Dept. of Earth and Planetary Sciences.
MICROMETEORITE DYNAMIC PYROMETAMORPHISM: NONSTOICHIOMETRIC CLINOENSTATITE (CLEN) Abstract Only
Frans J. M. Rietmeijer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1199-1200 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20716*# New Mexico Univ., Albuquerque. Dept. of Earth and Planetary Sciences.
MICROMETEORITE DYNAMIC PYROMETAMORPHISM: OBSERVATION OF A THERMAL GRADIENT IN IRON-NICKEL SULFIDE Abstract Only
Frans J. M. Rietmeijer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1201-1202 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20721*# Geological Survey, Flagstaff, AZ.
THE MANSON IMPACT CRATER: ESTIMATION OF THE ENERGY OF FORMATION, POSSIBLE SIZE OF THE IMPACTING ASTEROID OR COMET, AND EJECTA VOLUME AND MASS Abstract Only
D. J. Roddy, E. M. Shoemaker, and R. R. Anderson (Geological Survey, Iowa City, IA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1211-1212 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20726*# Open Univ., Milton (England). Dept. of Geological Sciences.
A CARBON AND NITROGEN ISOTOPE STUDY OF CARBONACEOUS VEIN MATERIAL IN UREILITE METEORITES Abstract Only
S. S. Russell, J. W. Arden, I. A. Franchi, and C. T. Pillinger *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1221-1222 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20729*# Planetary Science Inst., Tucson, AZ.
ASTEROID COLLISIONS: TARGET SIZE EFFECTS AND RESULTANT VELOCITY DISTRIBUTIONS Abstract Only
Eileen V. Ryan *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1227-1228 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20735*# Moscow State Univ. (Russia).
PRELIMINARY ESTIMATION OF TAGAMITE COOLING CONDITIONS (PUCHEZH-KATUNKI ASTROBLEME, RUSSIA) Abstract Only
L. Sazonova, V. Feldman, and N. Korotaeva *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1239-1240 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20741*# California Univ., Los Angeles. Inst. of Geophysics and Planetary Physics.
IRIDIUM IN SEDIMENTS CONTAINING LARGE ABUNDANCES OF AUSTRALASIAN MICROTEKTITES FROM DSDP HOLE 758B IN THE EASTERN INDIAN OCEAN AND FROM DSDP HOLE 769A IN THE SULU SEA Abstract Only
Gerhard Schmidt, Lei Zhou, and John T. Wasson *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1251 (For primary document see N94-20636 05-91)
(Grant NSF EAR-91-19065)
Avail: CASI HC A01/MF A06

N94-20746*# Maryland Univ., College Park. Dept. of Astronomy.
C2, CN AND DUST IN COMET WILSON (1987VII) Abstract Only
R. Schulz, M. F. AHearn, P. V. Birch (Perth Observatory, Australia.), C. Bowers (Perth Observatory, Australia.), M. Kempin (Perth Observatory, Australia.), and R. Martin (Perth Observatory, Australia.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1261-1262 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20749*# Hawaii Univ., Honolulu. Dept. of Geology and Geophysics.
POST-METAMORPHIC BRECCIATION IN TYPE 3 ORDINARY CHONDRITES Abstract Only
E. R. D. Scott, T. J. McCoy, and K. Keil *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1267-1268 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20750*# Arkansas Univ., Fayetteville. Cosmochemistry Group.
CATHODOLUMINESCENCE OBSERVATIONS OF IN SITU AQUEOUS DESTRUCTION OF CHONDRULES IN THE MURCHISON CM CHONDRITE Abstract Only
Derek W. G. Sears, Paul H. Benoit, Lu Jie, and Andrew S. R. Sears *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1269-1270 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20752*# Academy of Sciences (USSR), Moscow. Inst. of Geochemistry and Analytical Chemistry.
LUNAR BASALT METEORITE EET 87521: PETROLOGY OF THE CLAST POPULATION Abstract Only
A. S. Semenova, M. A. Nazarov, and N. N. Kononkova *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1273-1274 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20756*# Centre d'Etudes de Limeil-Valenton, Villeneuve Saint-Georges (France). Commissariat a L'Energie Atomique.
MOLECULAR EQUILIBRIA AND CONDENSATION SEQUENCES IN CARBON RICH GASES Abstract Only
C. M. Sharp and G. J. Wasserburg (California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1281-1282 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20764*# National Science Museum, Tokyó (Japan).
THE CHONDRITE MIHONOSEKI: NEW OBSERVED FALL Abstract Only
Masako Shima, A. Okada (Okayama Univ., Japan.), and K. Nagao (Okayama Univ., Japan.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1297-1298 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20768*# Scripps Institution of Oceanography, La Jolla, CA.
FE-60 AND THE EVOLUTION OF EUCRITES Abstract Only
A. Shukolyukov and G. W. Lugmair *In* Lunar and Planetary Inst.,

Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1305-1306 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20770*# Chicago Univ., IL. Dept. of Geophysical Sciences.
PETROGRAPHY AND ORIGIN OF REFRACTORY INCLUSIONS FROM THE MURRAY AND MURCHISON C2 CHONDRITES Abstract Only
S. B. Simon, L. Grossman, and A. Hsu (Illinois Mathematics and Science Academy, Aurora.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1309-1310 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20773*# Oberlin Coll., OH. Dept. of Geology.
SIZE DISTRIBUTIONS AND AERODYNAMIC EQUIVALENCE OF METAL CHONDRULES AND SILICATE CHONDRULES IN ACFER 059 Abstract Only
William R. Skinner and James M. Leenhouts (Arizona Univ., Tucson.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1315-1316 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20788*# Chicago Univ., IL. Dept. of Geophysical Sciences.
Fe/Mn IN OLIVINE OF CARBONACEOUS METEORITES Abstract Only
Ian M. Steele *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1345-1346 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20790*# Muenster Univ. (Germany). Inst. of Physikalisches.
MULTIELEMENT ANALYSIS OF INTERPLANETARY DUST PARTICLES USING TOF-SIMS Abstract Only
T. Stephan, W. Kloeck, E. K. Jessberger (Max-Planck-Inst. fuer Kernphysik, Heidelberg, Germany.), H. Rulle, and J. Zehnpfenning *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1349-1350 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20793*# California Inst. of Tech., Pasadena.
VOLATILE LOSS FROM ACCRETING ICY PROTOPLANETS Abstract Only
D. J. Stevenson *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1355-1356 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20795*# California Inst. of Tech., Pasadena. Div. of Geological and Planetary Sciences.
THE Sm-Nd SYSTEMATICS OF SILICATE INCLUSIONS IN IRON METEORITES: RESULTS FROM CADDO (IAB) Abstract Only
Brian W. Stewart, D. A. Papanastassiou, and G. J. Wasserburg *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1359-1360 (For primary document see N94-20636 05-91)
(Grant NAG9-43)
(Contrib-5241(804)) Avail: CASI HC A01/MF A06

N94-20812*# Tokyo Univ. (Japan). Mineralogical Inst.
TI-BEARING OXIDE MINERALS IN LUNAR METEORITE Y793169 WITH THE VLT AFFINITY Abstract Only
Hiroshi Takeda, Tomoko Arai, and Kazuto Saiki *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1393-1394 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20813*# National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.
A NEW ANTARCTIC METEORITE WITH CHROMITE, ORTHOPYROXENE AND METAL WITH REFERENCE TO A FORMATION MODEL OF S ASTEROIDS Abstract Only
Hiroshi Takeda (Tokyo Univ., Japan.), Kazuto Saiki (Tokyo Univ., Japan.), Mayumi Otsuki (Tokyo Univ., Japan.), and Takahiro Hiroi *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1395-1396 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20817*# Baylor Univ., Waco, TX. Dept. of Physics.
DETERMINATION OF PARAMETERS FOR HYPERVELOCITY DUST GRAINS ENCOUNTERED IN NEAR-EARTH SPACE Abstract Only
William G. Tanner, Carl R. Maag (Science Applications International Corp., Glendora, CA.), W. Merle Alexander, and Patricia Sappenfield *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1403-1404 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20823*# Belorussian State Univ., Minsk (Belarus).
THE SAND BAG MODEL OF THE DISPERSION OF THE COSMIC BODY IN THE ATMOSPHERE Abstract Only
A. V. Teterev and I. V. Nemchinov (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1415-1416 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20824*# Belorussian State Univ., Minsk (Belarus).
ATMOSPHERIC BREAKUP OF A SMALL COMET IN THE EARTH'S ATMOSPHERE Abstract Only
A. V. Teterev, N. I. Misychenko, L. V. Rudak, G. S. Romanov (Institute of Heat and Mass Transfer, Minsk, Belarus.), A. S. Smetannikov (Institute of Heat and Mass Transfer, Minsk, Belarus.), and I. V. Nemchinov (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1417-1418 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20827*# Cologne Univ. (Germany).
SYNOPTIC OBSERVATIONS OF NEAR SURFACE PROCESSES OF AN INSOLATED ICE-DUST BODY UNDER SPACE CONDITIONS: THE CASE OF KOSI 9 AND 10 Abstract Only
K. Thiel, G. Koelzer, E. Lorenz (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Berlin, Germany.), H. Kochan (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne, Germany.), J. Gebhard (Max-Planck-Inst. fuer Kernphysik, Heidelberg, Germany.), and E. Gruen (Max-Planck-Inst. fuer Kernphysik, Heidelberg, Germany.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1423-1424 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20828*# National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.
COMETARY INTERPLANETARY DUST PARTICLES? AN UPDATE ON CARBON IN ANHYDROUS IDPS Abstract Only
K. L. Thomas (Lockheed Engineering and Sciences Co., Houston, TX.), L. P. Keller, G. E. Blanford (Houston Univ., TX.), and D. S. McKay *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1425-1426 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20834*# Geological Survey, Denver, CO.
THE U-Th-Pb, Sm-Nd, AND Ar-Ar ISOTOPIC SYSTEMATICS OF LUNAR METEORITE YAMATO-793169 Abstract Only
Noriko Torigoye, Keji Misawa, G. Brent Dalrymple (Geological Survey, Menlo Park, CA.), and Mitsunobu Tatsumoto *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1437-1438 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20836*# Lockheed Engineering and Sciences Co., Houston, TX.
THE PARENT MAGMA OF THE NAKHLA (SNC) METEORITE: RECONCILIATION OF COMPOSITION ESTIMATES FROM MAGMATIC INCLUSIONS AND ELEMENT PARTITIONING Abstract Only
A. H. Treiman *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1441-1442 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20837*# Jet Propulsion Lab., California Inst. of Tech., Pasadena.
INTACT CAPTURE OF HYPERVELOCITY PARTICLES ON SHUTTLE Abstract Only
P. Tsou, D. E. Brownlee (Washington Univ., Seattle.), and A. L. Albee (California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1443-1444 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20840*# Arizona State Univ., Tempe. Dept. of Geology.
IMPACT-INDUCED DEVOLATILIZATION OF CaSO4 ANHYDRITE AND IMPLICATIONS FOR K-T EXTINCTIONS: PRELIMINARY RESULTS Abstract Only
James A. Tyburczy and Thomas J. Ahrens (California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1449-1450 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20841*# European Space Research Organization, Noordwikj (Netherlands). Dept. of Space Science.
MEASUREMENTS OF THE DIELECTRIC PROPERTIES OF SIMULATED COMET MATERIAL AS PART OF THE KOSI 10 EXPERIMENT Abstract Only
S. Ulamec, H. Svedhem, and H. Kochan (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne, Germany.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1451-1452 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20844*# Academy of Sciences (USSR), Moscow. Inst. of Geochemistry and Analytical Chemistry.
ON MODELLING NUCLEAR REACTIONS IN METEORITES Abstract Only
G. K. Ustinova and A. K. Lavrukhina *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1457-1458 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20845*# Jet Propulsion Lab., California Inst. of Tech., Pasadena.
IMPS ALBEDO AND DIAMETER FOR ASTEROID 243 IDA Abstract Only
G. J. Veeder and E. F. Tedesco (Mission Research Corp., Santa Barbara, CA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1459-1460 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20846*# Open Univ., Milton (England).
ARE THE C DELTA LIGHT NITROGEN AND NOBLE GASES LOCATED IN THE SAME CARRIER? Abstract Only
A. B. Verchovsky, S. S. Russell, C. T. Pillinger, A. V. Fisenko (Academy of Sciences, USSR, Moscow.), and Yuri A. Shukolyukov (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1461-1462 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20848*# National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.
COMPARISON OF VISIBLE AND NEAR-INFRARED REFLECTANCE SPECTRA OF CM2 CARBONACEOUS CHONDRITES AND PRIMITIVE ASTEROIDS Abstract Only
F. Vilas, T. Hiroi, and M. E. Zolensky *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1465-1466 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20849*# Academy of Sciences (USSR), Moscow. Inst. of Physics of the Earth.
RECONDENSATION IN THE EARLY SOLAR SYSTEM: PHYSICAL CONDITIONS AND SOURCE MATERIAL Abstract Only
A. V. Vityazev, V. A. Dorofeyeva, and A. B. Makalkin *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1467-1468 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20854*# Maryland Univ., College Park. Dept. of Geology.
RHENIUM-OSMIUM ISOTOPE SYSTEMATICS OF ORDINARY CHONDRITES AND IRON METEORITES Abstract Only
R. J. Walker, J. W. Morgan (Geological Survey, Reston, VA.), M. F. Horan (Geological Survey, Reston, VA.), and J. N. Grossman (Geological Survey, Reston, VA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1477-1478 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20857*# National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.
CONSORTIUM STUDY OF LUNAR METEORITES YAMATO-793169 AND ASUKA-881757: GEOCHEMICAL EVIDENCE OF MUTUAL SIMILARITY, AND DISSIMILARITY VERSUS OTHER MARE BASALTS Abstract Only
Paul H. Warren (California Univ., Los Angeles.) and Marilyn M. Lindstrom *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1483-1484 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20858*# National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.
MAGNETIC RECORD IN CHONDRITE METEORITES Abstract Only
P. J. Wasilewski, J. L. Faris, and M. V. OBryan *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1485-1486 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20860*# California Univ., Los Angeles. Inst. of Geophysics and Planetary Physics.
MULTIPLICITY OF CHONDRULE HEATING EVENTS AND THE COARSENING OF CHONDRULE TEXTURES Abstract Only
John T. Wasson *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1489-1490 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20861*# National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.
EQUILIBRIUM AND FRACTIONAL CRYSTALLIZATION OF A PRIMITIVE SHERGOTTITE COMPOSITION Abstract Only
L. E. Wasylenki (California Inst. of Tech., Pasadena.), J. H. Jones, L. Le (Lockheed Engineering and Sciences Co., Houston, TX.), and A. J. G. Jurewicz (Lockheed Engineering and Sciences Co., Houston, TX.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1491-1492 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20865*# Arizona Univ., Tucson. Planetary Science Inst.
COAGULATION OF GRAINS IN STATIC AND COLLAPSING PROTOSTELLAR CLOUDS Abstract Only
S. J. Weidenschilling and T. V. Ruzmaikina (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1499-1500 (For primary

document see N94-20636 05-91)
(Contract NASw-4616)
Avail: CASI HC A01/MF A06

N94-20866*# American Museum of Natural History, New York, NY. Dept. of Mineral Sciences.
THE FORMATION OF FeO-RICH PYROXENE AND ENSTATITE IN UNEQUILIBRATED ENSTATITE CHONDRITES: A PETROLOGIC-TRACE ELEMENT (SIMS) STUDY Abstract Only
M. K. Weisberg, M. Prinz, R. A. Fogel, and N. Shimizu (Woods Hole Oceanographic Inst., MA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1501-1502 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20869*# National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.
WEATHERING FEATURES AND SECONDARY MINERALS IN ANTARCTIC SHERGOTTITES ALHA77005 AND LEW88516 Abstract Only
Susan J. Wentworth (Lockheed Engineering and Sciences Co., Houston, TX.) and James L. Gooding *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1507-1508 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20871*# Carnegie Institution of Washington, DC.
VARIETY IN PLANETARY SYSTEMS Abstract Only
George W. Wetherill *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1511-1512 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20877*# Carnegie Institution of Washington, DC.
EQUILIBRIUM MODELS OF MASS DISTRIBUTION AND COLLISIONAL LIFETIMES OF ASTEROIDS Abstract Only
David R. Williams and George Wetherill *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1523-1524 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

N94-20884*# California State Univ., Fullerton.
LREE VARIABILITY IN CM MATRICES: ANOTHER LOOK AT METEORITE COMPACTION AGES Abstract Only
Dorothy S. Woolum, Karen Poelstra, C. Alexander (Washington Univ., Saint Louis, MO.), and T. Ireland (Australian National Univ., Canberra.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1537-1538 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A STUDY OF SATURN'S E-RING PARTICLES USING THE VOYAGER 1 PLASMA WAVE INSTRUMENT
D. Tsintikidis, W. S. Kurth, D. A. Gurnett, and D. D. Barbosa (California Univ., Los Angeles.) Sep. 1993 50 p
(Contract JPL-959193)
(NASA-CR-194694; NAS 1.26:194694; U-of-Iowa-93-19) Avail: CASI HC A03/MF A01

The flyby of Voyager 1 at Saturn resulted in the detection of a large variety of plasma waves, e.g., chorus, hiss, and electron cyclotron harmonics. Just before the outbound equator crossing, at about 6.1 R(sub s), the Voyager 1 plasma wave instrument detected a strong, well-defined low-frequency enhancement. Initially it was suggested that plasma waves might be responsible for the spectral feature but more recently dust was suggested as at least a partial contributor to the enhancement. In this report we present evidence which supports the conclusion that dust contributes to the low-frequency enhancement. A new method has been used to derive the dust impact rate. The method relies mainly on the 16-channel spectrum analyzer data. The few wide band waveform observations available (which have been used to study dust impacts during the Voyager 2 ring plane crossing) were useful for calibrating the impact rate from the spectrum analyzer data. The mass and, hence, the size of the dust particles were also obtained by analyzing the response of the plasma wave spectrum analyzer. The results show that the region sampled by Voyager 1 is populated by dust particles that have rms masses of up to few times 10(exp -11) g and sizes of up to a few microns. The dust particle number density is on the order of 10(exp -3) m(exp 3). The optical depth of the region sampled by the spacecraft is 1.04 x 10(exp -6). The particle population is centered about 2500 km south of the equatorial plane and has a north-south thickness of about 4000 km. Possible sources of these particles are the moons Enceladus and Tethys whose orbits lie within the E-ring radial extent. These results are in reasonable agreement with photometric studies and numerical simulations. Author

WORKSHOP ON THE MARTIAN NORTHERN PLAINS: SEDIMENTOLOGICAL, PERIGLACIAL, AND PALEOCLIMATIC EVOLUTION Abstracts Only
Jeffrey S. Kargel, ed. (Geological Survey, Flagstaff, AZ.), Jeffrey Moore, ed. (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.), and Timothy Parker, ed. (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 1993 29 p Workshop held in Fairbanks, AK, 12-14 Aug. 1993; sponsored by MSATT Study Group and Alaska Univ.
(Contract NASw-4574)
(NASA-CR-194831; NAS 1.26:194831; LPI-TR-93-04-Pt-1) Avail: CASI HC A03/MF A01

Papers that have been accepted for presentation at the Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution, on 12-14 Aug. 1993 in Fairbanks, Alaska are included. Topics covered include: hydrological consequences of ponded water on Mars; morphological and morphometric studies of impact craters in the Northern Plains of Mars; a wet-geology and cold-climate Mars model: punctuation of

a slow dynamics approach to equilibrium; the distribution of ground ice on Mars; and stratigraphy of the Martian Northern Plains. For individual titles, see N94-20383 through N94-20402.

HYDROLOGICAL CONSEQUENCES OF PONDED WATER ON MARS Abstract Only
V. R. Baker *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 1-2 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Although geomorphological evidence for ancient highly active water cycling has long been obvious for Mars, geochemical analyses have only recently been found to be consistent with this fact. One approach to understanding the geomorphological evidence has been to estimate the total volume of the Martian hydrosphere. I will discuss an approach focused on the history of changing water processes on the planet, and on the understanding of those processes in a global sense. Author (revised)

MORPHOLOGIC AND MORPHOMETRIC STUDIES OF IMPACT CRATERS IN THE NORTHERN PLAINS OF MARS Abstract Only
N. G. Barlow *In its* Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 2-3 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Fresh impact craters in the northern plains of Mars display a variety of morphologic and morphometric properties. Ejecta morphologies range from radial to fluidized, interior features include central peaks and central pits, fluidized morphologies display a range of sinuosities, and depth-diameter ratios are being measured to determine regional variations. Studies of the martian northern plains over the past five years have concentrated in three areas: (1) determining correlations of ejecta morphologies with crater diameter, latitude, and underlying terrain; (2) determining variations in fluidized ejecta blanket sinuosity across the planet; and (3) measurement of depth-diameter ratios and determination of regional variations in this ratio. Author (revised)

CALDERAS PRODUCED BY HYDROMAGMATIC ERUPTIONS THROUGH PERMAFROST IN NORTHWEST ALASKA Abstract Only
J. E. Beget *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 3 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Most hydromagmatic eruptions on Earth are generated by interactions of lava and ground or surface water. This eruptive process typically produces craters 0.1-1 km in diameter, although a few as large as 1-2 km were described. In contrast, a series of Pleistocene hydromagmatic eruptions through 80-100-m-thick permafrost on the Seward Peninsula of Alaska produced four craters 3-8 km in diameter. These craters, called the Espenberg maars, are the four largest maars known on Earth. The thermodynamic properties of ground ice influence the rate and amount of water melted during the course of the eruption. Large quantities of water are present, but only small amounts can be melted at any time to interact with magma. This would tend to produce sustained and highly explosive low water/magma (fuel-coolant) ratios during the eruptions. An area of 400 km(sub 2) around the Alaskan maars shows strong reductions in the density of thaw lakes, ground ice, and other surface manifestations of permafrost because of deep burial by coeval tephra falls. The unusually large Espenberg maars are the first examples of calderas produced by hydromagmatic eruptions. These distinctive landforms can apparently be used as an indicator of the presence of permafrost at the time of eruption. Author (revised)

MILANKOVITCH INSULATION FORCING AND CYCLIC FORMATION OF LARGE-SCALE GLACIAL, FLUVIAL, AND EOLIAN LANDFORMS IN CENTRAL ALASKA Abstract Only
J. E. Beget *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 3 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Continuous marine and ice-core proxy climate records indicate that the Earth's orbital geometry modulates long-term changes. Until recently, little direct evidence has been available to demonstrate correlations between Milankovitch cycles and large-scale terrestrial landforms produced during worldwide glaciations. In central Alaska large areas of loess and sand fill valleys and basins near major outwash streams. The streams themselves are bordered by sets of outwash terraces, and the terraces grade up valley into sets of moraines. The discovery of the Stampede tephra (approximately 175,000 yr ago) reworked within push moraines of the Lignite Creek glaciation suggests that this event correlates with the glaciation of marine isotope stage 6. A new occurrence of the Old Crow tephra (approximately 140,000 yr ago) on the surface of the oldest outwash terrace of the Tanana River, correlated with Delta glaciation, suggests this event also occurred at this time. The penultimate Healy glaciation apparently correlates with marine isotope stage 4, while radiocarbon dates indicate the latest Pleistocene moraines correlate with marine isotope stage 2. Recognition of the importance of orbital forcing to the cyclical formation of glacial landforms and landscapes can help in interpretations of remotely sensed glacial and proglacial land forms. Author (revised)

THE FATE OF WATER DEPOSITED IN THE LOW-LYING NORTHERN PLAINS Abstract Only
M. H. Carr *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 3-4 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Many large outflow channels terminate in the low-lying northern plains. If the outflow channels formed by running water, as appears likely, then standing bodies of water must have accumulated at the ends of the channels. Most of the observed channels, and hence the bodies of water, are post-Noachian. They formed after the period for which we have the most abundant evidence of climate change. While it has been speculated that the post-Noachian period has experienced large, episodic, climatic excursions, this paper takes the more conservative view that the climatic conditions on Mars, at least from mid-Hesperian onward, were mostly similar to the climatic conditions that prevail in the present epoch. Thus obliquity variations are taken into account, but massive climate changes induced by the floods are considered so improbable that they are ignored. Author (revised)

EVIDENCE FOR AN ICE SHEET/FROZEN LAKE IN UTOPIA PLANITIA, MARS Abstract Only
M. G. Chapman *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 4-5 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Previous workers noted evidence for a lacustrine basin in Utopia Planitia, Mars. Geomorphic features within the basin that collectively suggest that water or ice may once have been present include channels within the basin, channels peripheral to the basin, etched basin floor, 'thumbprint' terrain (whorled patterns), polygonal outlines, smooth floors (infilled), shoreline indicators (terraces, platforms, lineaments), and small cratered cones (pseudo craters or pingos). The authors interpret these data to suggest that the basin may have been the locus of a large paleolake in the northern lowlands of Mars. Alternatively, the area was proposed to be part of an ancient circumpolar ocean. The hypothetical paleolake was probably frozen to some depth. In fact, features now present at its boundaries suggest that the edges may have been frozen solid. Plains units at the southwestern boundary of Utopia Planitia show ridges that were compared with those that form at the mouths of Antarctic ice streams, thumbprint terrain, and young, high deposits having lobate margins that suggest mudflows. Thumbprint terrains were interpreted as recessional moraines, ice-pushed ridges, or subglacially eroded tunnel valleys with eroded eskers. At the east boundary of Utopia Planitia, geologic mapping at 1:500,000 scale of the Granicus Valles area (MTM quadrangles 30227, 30222, and 25227) indicates the presence of a basal scarp around the northwest flank

of Elysium that formed the east boundary of an ancient ice sheet.

A WET-GEOLOGY AND COLD-CLIMATE MARS MODEL: PUNCTUATION OF A SLOW DYNAMIC APPROACH TO EQUILIBRIUM Abstract Only
J. S. Kargel *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 5-7 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

It was suggested that Mars may have possessed a relatively warm humid climate and a vigorous hydrological cycle involving meteoric precipitation, oceans, and continental ice sheets. Baker hypothesized that these geologically active conditions may have been repeated several times; each of these dynamic epochs was followed by a collapse of the climate and hydrologic cycle of Mars into essentially current conditions, completing what is termed a 'Baker cycle'. The purpose is to present an endmember possibility that Martian glacial landscapes, including some that were previously considered to have formed under warm climatic conditions, might be explained by processes compatible with an extremely cold surface. Two aspects of hypothesized Martian glacial terrains were cited as favoring a warm climate during Baker cycles: (1) the formation of some landscapes, including possible eskers, tunnel channels, drumlins, and outwash plains, appears to have required liquid water, and (2) a liquid-surfaced ocean was probably necessary to feed the glaciers. The requirement for liquid water, if these features were correctly interpreted, is difficult to avoid; it is entirely possible that a comparatively warm climate was involved, but it is not clear that formation of landforms by wet-based glaciers actually requires a warm climate. Even less certain is the supposed requirement for liquid oceans. Formation of glaciers only requires a source of water or ice to supply an amount of precipitation that exceeds losses due to melting and sublimation. At Martian temperatures precipitation is very low, but so are melting and sublimation, so a large body of ice that is unstable with respect to sublimation may take the role of Earth's oceans in feeding the glaciers. Recent models suggest that even current Martian polar caps, long thought to be static bodies of ice and dust, might actually be slow-moving, cryogenic continental glaciers. Is it possible that subglacial processes beneath cryogenic (but wetbased) ice sheets formed the hypothesized Martian glacial landscapes? Author (revised)

POSSIBLE OCCURRENCE AND ORIGIN OF MASSIVE ICE IN UTOPIA PLANITIA Abstract Only
J. S. Kargel and F. M. Costard (Centre National de la Recherche Scientifique, Caen, France.) *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 7-8 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

F. M. Costard recently discovered a large field of possible thermokarst depressions near latitude 45 deg N, longitude 270 deg, in western Utopia Planitia. Oval to circular pits are typically 300-1000 m across and approximately 25 m deep; larger depressions, 3-5 km across, are compound and seem to have formed by coalescence of smaller pits. Small domical hills occur on the floors of two pits. These depressions characteristically have steep, scalloped edges and one or more inner benches. Truncation relations of the benches suggest a discontinuous, lenslike stratification of the material in which the pits are developed. Based on a close analogy in form and scale with coalesced thawlake basins (alases) on Earth, the Martian pits may have formed by thermophysical interactions of pooled water with ice-rich permafrost. This interpretation is not unique; sublimation of ice-rich permafrost or possibly even eolian processes acting on ice-free material might have formed the pits. However, the regional setting contains many other indications of massive ice. Some of these features are examined. Author (revised)

ICE IN THE NORTHERN PLAINS: RELIC OF A FROZEN OCEAN? Abstract Only
B. K. Lucchitta *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 9-10 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Viking images revealed many features in the northern plains and along their boundary that early investigators believed to be formed by ice-related processes. The features are possible pingos, pseudocraters, table mountains and moberg ridges, thermokarst depressions, moraines, patterned ground, and lobate aprons that suggest viscous flow such as that of ice or rock glaciers. More recently, many of these features were reinterpreted as related to sedimentation in hypothetical former polar lakes, oceans, or alluvial plains or as shoreline features of associated water bodies. Some evidence that points toward the existence of former bodies of standing water in the northern plains, but is also consistent with the idea that these bodies were ice covered or completely frozen is reviewed. OBSERVED CLIMATIC ACTIVITY PERTAINING TO THE EVOLUTION OF THE NORTHERN PLAINS Abstract Only
L. J. Martin and P. B. James (Toledo Univ., OH.) *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 10 Sponsored in part by Space Telescope Inst. (For primary document see N94-20382 05-91)
(Grants NAGw-2257; NAGw-3311)
Avail: CASI HC A01/MF A01

Although most of the landforms observed by Viking were probably formed long before the advent of present climatic conditions, it is possible that some modifications occurred more recently and may continue to the present. Also, present climate activity provides another dataset for hypothesizing earlier climatic conditions. Observations of climatic activity in the northern plains from 1905 to 1993 are summarized. Data from Earthbound telescopes and from spacecraft, including the Hubble Space Telescope (HST), were used. Author (revised)

A MODEL FOR THE ORIGIN OF MARTIAN POLYGONAL TERRAIN Abstract Only
G. E. McGill *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 10-12 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Extensive areas of the Martian northern plains in Utopia and Acidalia Planitiae are characterized by 'polygonal terrain.' Polygonal terrain consists of material cut by complex troughs defining a pattern resembling mudcracks, columnar joints, or frost-wedge polygons on the Earth. However, the Martian polygons are orders of magnitude larger than these potential Earth analogs, leading to severe mechanical difficulties for genetic models based on simple analogy arguments. Stratigraphic studies show that the polygonally fractured material in Utopia Planitia was deposited on a land surface with significant topography, including scattered knobs and mesas, fragments of ancient crater rims, and fresh younger craters. Sediments or volcanics deposited over topographically irregular surfaces can experience differential compaction producing drape folds. Bending stresses due to these drape folds would be superposed on the pervasive tensile stresses due to desiccation or cooling, such that the probability of fracturing is enhanced above buried topographic highs and suppressed above buried topographic lows. Thus it was proposed that the scale of the Martian polygons is controlled by the spacing of topographic highs on the buried surface rather than by the physics of the shrinkage process. THE DISTRIBUTION OF GROUND ICE ON MARS Abstract Only
M. T. Mellon and B. M. Jakosky *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 12 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

A wealth of geologic evidence indicates that subsurface water ice has played an important role in the evolution of Martian landforms. Theoretical models of the stability of ground ice show that in the near-surface regolith ice is currently stable at latitudes poleward of about +/- 40 deg and below a depth of a few centimeters to a meter, with some variations with longitude. If ice is not previously present at a particular location where it is stable, atmospheric water will diffuse into the regolith and condense as ice, driven by the annual subsurface thermal oscillations. The lower boundary

of this ice deposit is found to occur at a depth (typically a few meters) where the annual thermal oscillations give way to the geothermal gradient. In the equatorial regions near-surface ice is currently not stable, resulting in the sublimation of any existing ice and subsequent loss to the atmosphere. However, subliming ice might be maintained at a steady-state depth, where diffusion and loss to the atmosphere are balanced by resupply from a possible deeper source of water (either deeper, not yet depleted, ice deposits or ground water). This depth is typically a few tens to hundreds of meters and depends primarily on the surface temperature and the nature of the geothermal gradient, being deeper for a higher surface temperature and a lower geothermal gradient. Such an equatorial deposit is characterized by the regolith ice content being low nearer the surface and increasing with depth in the deposit. Oscillations in the orbit will affect this picture of ground ice in two ways: by causing periodic changes in the pattern of near-surface stability and by producing subsurface thermal waves that may be capable of driving water ice deeper into the regolith. A MARINE SEDIMENTARY MODEL FOR THE EVOLUTION OF THE NORTHERN PLAINS Abstract Only
T. J. Parker and D. S. Gorsline *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 12-14 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

For the purpose of focusing the following discussion, we begin with the reasonable assumption that landforms interpreted to be shorelines can be considered to be as diagnostic of former water levels within the northern plains of Mars as lava flows are of former volcanism. Once (or if) this interpretation of these features becomes more generally accepted and the compositional and topographic datasets for Mars improve, their distribution can be used to make valuable independent estimates of the planet's water budget by providing quantitative measures of surface reservoir volumes at specific instances in Martian history. The problem is approached from a consideration of the basin's volume and its implied requirement on juvenile water sources and channel discharges, rather than the other way around. Author (revised)

CRYOPLANATION TERRACES OF INTERIOR AND WESTERN ALASKA Abstract Only
R. D. Reger *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 14-15 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Cryoplanation terraces are step- or table like residual landforms consisting of a nearly horizontal bedrock surface covered by a thin veneer of rock debris and bounded by ascending or descending scarps or both. Among examples studied, rubble-covered scarps range in height from 3 to 76 m and slope from 9 deg to 32 deg; nearly vertical scarps exist where bedrock is exposed or thinly buried. Simple transverse nivation hollows, which are occupied by large seasonal snow banks, commonly indent the lower surfaces of sharply angular ascending scarps. Terrace treads slope from 1 deg to 10 deg and commonly cut across bedrock structures such as bedding, rock contacts, foliation, joints, faults, and shear zones. Debris on terrace treads is generally 0.8-2.5 m thick. Permafrost table is generally present from 0.5 to 2 m below the tread surface. Permafrost is shallowest in the floors of nivation hollows and deepest in the well-drained margins of terrace treads. Side slopes of cryoplanation terraces are shallowly buried bedrock surfaces that are littered with a variety of mass-movement deposits. Author (revised)

THE THUMBPRINT TERRAIN: WHAT WILL MARS OBSERVER TELL US? Abstract Only
M. W. Schaefer *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 15 Prepared in cooperation with Maryland Univ., College Park (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Some of the more puzzling features seen on Mars are those known as curvilinear features or 'thumb print' terrain, types of patterned ground found in the northern plains. The thumbprint terrain, named for its resemblance to the lines of a human thumbprint is found on what appears to be level, relatively low-lying ground near the crustal dichotomy boundary. It is often found near the termini of large channels. There are three types of thumbprint terrain in the classification of Rossbacher and Judson. The first consists of ridges and depressions about a kilometer wide, separated by a few kilometers, and with an apparent relief of 40-100 m. The second consists of steep-sided, flat-floored depressions about a kilometer wide, separated by a few kilometers, and with an apparent relief of 10-290 m. The third consists only of albedo markings, with a typical scale of about a kilometer. Many models were proposed to explain the origin of this terrain. It was suggested that it was caused by lava flows, removal of debris mantles, glaciers, or karst. However, the most popular models at present involve the action of subsurface ice to form such thermokarst features as striped ground, solifluction lobes, and/or linear, ice-cored ridges. There are several instruments on the Mars Observer spacecraft that will be able to provide us with information useful in distinguishing between these models. Author (revised)

STRATIGRAPHY OF THE MARTIAN NORTHERN PLAINS Abstract Only
K. L. Tanaka *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 15-17 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

The northern plains of Mars are roughly defined as the large continuous region of lowlands that lies below Martian datum, plus higher areas within the region that were built up by volcanism, sedimentation, tectonism, and impacts. These northern lowlands span about 50 x 10(exp 6) km(sup 2) or 35 percent of the planet's surface. The age and origin of the lowlands continue to be debated by proponents of impact and tectonic explanations. Geologic mapping and topical studies indicate that volcanic, fluvial, and eolian deposition have played major roles in the infilling of this vast depression. Periglacial, glacial, fluvial, eolian, tectonic, and impact processes have locally modified the surface. Because of the northern plains' complex history of sedimentation and modification, much of their stratigraphy was obscured. Thus the stratigraphy developed is necessarily vague and provisional: it is based on various clues from within the lowlands as well as from highland areas within and bordering the plains. The results are summarized. Author (revised)

SEISMIC-TRIGGERING HISTORY OF THE CATASTROPHIC OUTFLOWS IN THE CHRYSE REGION OF MARS Abstract Only
S. M. Clifford and K. L. Tanaka (Geological Survey, Flagstaff, AZ.) *In its* Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 17-18 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

Much attention was recently focused on the Chryse outflow channels as the source for an ocean or large lakes in the northern plains of Mars. A critical question is whether the channels formed quickly and in concert or sporadically. Crosscutting relations demonstrate multiple episodes of channel formation for some of the channels; however, for most channels, the absence of high precision in the densities of superposed impact craters prevents precise reconstruction of the duration and sequence of channeling history. Another approach to addressing the groundwater discharge history is to evaluate the hypothetical storage of the Chryse aquifer system and its recharge and triggering histories. How outflow breakouts may have been triggered by relatively frequent, large marsquakes caused by faulting and impact is discussed. Author (revised)

A FORMATIONAL MODEL FOR THE POLYGONAL TERRAINS OF MARS: TAKING A CRACK AT THE GENESIS OF THE MARTIAN POLYGONS Abstract Only
M. L. Wenrich and P. R. Christensen *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 19-21 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

The mechanism for the genesis of the polygonal terrains in Acidalia and Utopia Planitia has long been sought: however, no completely satisfying model was put forth that characterizes the evolution of these complexly patterned terrains. The polygons are roughly hexagonal but some are not entirely enclosed by fractures. These polygonal features range in widths from approximately 5 to 20 km. Several origins were proposed that describe the polygon borders as desiccation cracks, columnar jointing in a cooled lava, or frost-wedge features. These tension-induced cracking hypotheses were addressed by Pechmann, who convincingly disputes these mechanisms of formation based on scale magnitude difficulties and morphology. Pechmann suggests instead that the cracks delineating the 5-20-km-wide polygons on the northern plains of Mars are graben resulting from deep-seated, uniform, horizontal tension. The difficulty with this hypothesis is that no analogous polygonal forms are known to have originated by tectonism on Earth. McGill and Hills propose that the polygonal terrains on Mars resulted from either rapid desiccation of sediments or cooling of volcanics coupled with differential compaction of the material over a buried irregular topographic surface. They suggest that fracturing was enhanced over the areas of positive relief and was suppressed above the topographic lows. McGill and Hills suggest that the spacing of the topographic highs primarily controls the size of the Martian polygons and the physics of the shrinkage process is a secondary concern. Ray et. al. conducted a terrestrial study of patterned ground in periglacial areas of the U.S. to determine the process responsible for polygonal ground formation. They developed a model for polygon formation in which convection of seasonal melt water above a permafrost layer, driven by an unstable density stratification, differentially melts the permafrost interface, causing it to become undulatory. BALLOON EXPLORATION OF THE NORTHERN PLAINS OF MARS NEAR AND NORTH OF THE VIKING 2 LANDING SITE Abstract Only
Frederick R. West *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 21 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

The next stage of exploratory surveying of the northern plains of Mars after the Mars Observer mission may best be done by Mars Balloon Exploration Vehicles (MBEV's) deployed in the atmosphere above the northern plains near and north of the Viking 2 lander (VL-2) landing site. This region of Mars is favorable for exploration by MBEV's for the following reasons: (1) the low surface elevation (approximately 2km, lower than the standard (zero) elevation of the Martian surface) provides atmospheric pressure sufficient to allow a MBEV to successfully operate and explore this region at the present stage of MBEV design and development; and (2) the relatively smooth nature of the northern plains terrain (few mountains, ridges, valleys, and craters) indicated so far by Mariner 9 and Viking Orbiter data seems adequate for operation of a MBEV when its SNAKE extension is in contact with the surface of one of these plains. The science objectives are presented. Author (revised)

GEOMORPHIC EVIDENCE FOR AN EOLIAN CONTRIBUTION TO THE FORMATION OF THE MARTIAN NORTHERN PLAINS Abstract Only
J. R. Zimbelman *In* Lunar and Planetary Inst., Workshop on the Martian Northern Plains: Sedimentological, Periglacial, and Paleoclimatic Evolution 1993 p 21-23 (For primary document see N94-20382 05-91)
Avail: CASI HC A01/MF A01

The northern plains of Mars have many morphologic characteristics that are uncommon or absent on the rest of the planet. Mariner 9 and Viking images obtained north of latitude 30 deg N revealed 'smooth' and 'mottled' plains of an uncertain origin. Some or all of the northern plains were interpreted to consist of lava plains intermixed with eolian and volcanic materials thick eolian mantles that buried portions of the mid latitudes periglacial deposits resulting from the presence of ground ice and as water-transported sediments derived from fluvial runoff, lacustrine deposition in standing bodies of water, or glacial runoff. The highest-resolution Viking images show many intriguing details that may provide clues to the origin of this complex and distinctive terrain. Some of the informative features present in the best Viking images, comparing the observations to what may be expected from various hypotheses of formation, are reviewed. While the results are not conclusive for any single hypothesis, eolian processes have played a major role in the erosion (and possibly deposition) of the materials that make up the surface exposures in the Martian northern plains. SO2 ON VENUS: IUE, HST AND GROUND-BASED MEASUREMENTS, AND THE ACTIVE VOLCANISM CONNECTION Abstract Only
C. Y. Na, E. S. Barker (Texas Univ., Austin.), S. A. Stern, and L. W. Esposito (Colorado Univ., Boulder.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1043-1044 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Magellan images have shown that the volcanic features are widespread over the surface of Venus. The question of whether there is active volcanism is important for understanding both the atmospheric and the geological processes on Venus. The thick cloud cover of Venus precludes any direct observation of active volcanoes even if they exist. The only means of monitoring the active volcanism on Venus at present seems to be remote sensing from Earth. Continuous monitoring of SO2 is important to establish the long term trend of SO2 abundance and to understand the physical mechanism responsible for the change. Derived from text

EVAPORATION IN EQUILIBRIUM, IN VACUUM, AND IN HYDROGEN GAS Abstract Only **c25**
Hiroko Nagahara *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1045-1046 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Evaporation experiments were conducted for SiO2 in three different conditions: in equilibrium, in vacuum, and in hydrogen gas. Evaporation rate in vacuum is about two orders of magnitude smaller than that in equilibrium, which is consistent with previous works. The rate in hydrogen gas changes depending on hydrogen pressure. The rate at 10 exp -7 bar of hydrogen pressure is as small as that of free evaporation, but at 10 exp -5 bar of hydrogen pressure it is larger than that in equilibrium. In equilibrium and in vacuum, the evaporation rate is limited by decomposition of SiO2 on the crystal surface, but it is limited by a diffusion process for evaporation in hydrogen gas. Therefore, evaporation rate of minerals in the solar nebula can be shown neither by that in equilibrium nor by that in vacuum. The maximum temperature of the solar nebula at the midplane at 2-3 AU where chondrites are believed to have originated is calculated to be as low as 150 K, 1500 K, or in between them. The temperature is, in any case, not high enough for total evaporation of the interstellar materials. Therefore, evaporation of interstellar materials is one of the most important processes for the origin and fractionation of solid materials. The fundamental process of evaporation of minerals has been intensively studied for these several years. Those experiments were carried out either in equilibrium or in vacuum; however, evaporation in the solar nebula is in hydrogen (and much smaller amount of helium) gas. In order to investigate evaporation rate and compositional (including isotopic) fractionation during evaporation, vaporization experiments for various minerals in various conditions are conducted. At first, SiO2 was adopted for a starting material, because

thermochemical data and its nature of congruent vaporization are well known. Experiments were carried out in a vacuum furnace system.

THE EREVAN HOWARDITE: PETROLOGY OF GLASSY CLASTS AND MINERAL CHEMISTRY Abstract Only **c25**
M. A. Nazarov and A. A. Ariskin *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1049-1050 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The Erevan howardite is a polymict regolith breccia containing xenoliths of carbonaceous chondrites. In this work, we studied glassy clasts, which could be considered as primary quenched melts, and mineral chemistry of the breccia. The study reveals that the Erevan howardite consists of common rocks of the HED suite. However, unique glassy clasts, which are present in some eucritic melts, were identified. The mineral chemistry and the simulation of crystallization of the melts suggest that the compositions of the melts reflect those of some primary lithologies of EPB.

IGNEOUS ROCK FROM SEVERNYI KOLCHIM (H3) CHONDRITE: NEBULAR ORIGIN Abstract Only **c90**
M. A. Nazarov, F. Brandstaetter (Naturhistorisches Museum, Vienna, Austria.), and G. Kurat (Naturhistorisches Museum, Vienna, Austria.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1055-1056 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The discovery of lithic fragments with compositions and textures similar to igneous differentiates in unequilibrated ordinary chondrites (UOC's) and carbonaceous chondrites (CC's) has been interpreted as to suggest that planetary bodies existed before chondrites were formed. As a consequence, chondrites (except, perhaps CI chondrites) cannot be considered primitive assemblages of unprocessed nebular matter. We report about our study of an igneous clast from the Severnyi Kolchim (H3) chondrite. The results of the study are incompatible with an igneous origin of the clast but are in favor of a nebular origin similar to that of chondrules.

Mare basalts returned by the Apollo 12 mission have been divided into 4 groups on the basis of mineralogy and whole-rock chemistry: olivine basalts; pigeonite basalts; ilmenite basalts; and feldspathic basalts. James and Wright and Rhodes et al. concluded that the olivine and pigeonite groups were co-magmatic and that the within group variations are due to fractional crystallization of olivine and minor Cr-spinel, with pigeonite replacing olivine in the pigeonite basalts. Rhodes et al. concluded that the parental compositions for these suites were probably represented by the vitrophyres, and the olivine basalts are comprised essentially of cumulates and the pigeonites of evolved end-members. However, Neal et al. have demonstrated, using trace-element considerations, that the Apollo 12 olivine and pigeonite suites are not related. The ilmenite basalts were studied extensively by Dungan and Brown who noted that both cumulates and evolved fractionates were present within this group. In their modeling, Dungan and Brown used the vitrophyre compositions as parents. Neal et al. demonstrated that the feldspathic suite was probably comprised of only one member - 12038. Herein, the ilmenite and olivine basalts are demonstrated to be the products of several non-modal partial melting events of a single source followed by closed-system fractional crystallization.

PETROGENESIS OF APOLLO 12 MARE BASALTS. PART 2: AN OPEN SYSTEM MODEL TO EXPLAIN THE PIGEONITE BASALT COMPOSITIONS Abstract Only **c25**
Clive R. Neal and Lawrence A. Taylor (Tennessee Univ., Knoxville.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1059-1060 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Original petrogenetic models suggested that the pigeonite basalts were the evolved equivalents of the olivine basalts. Rhodes et al. concluded that the olivine and pigeonite basalts were co-magmatic, but Neal et al. have demonstrated that these two basaltic groups are distinct and unrelated. The pigeonite suite is comprised of porphyritic basalts with a fine-grained ground mass and range continuously to coarse-grained microgabbros with ophitic to graphic textures. Although it was generally recognized that the pigeonite basalts were derived from the olivine basalts by olivine + minor Cr-spinel fractionation, the compositional gap between these groups is difficult to reconcile with such a model. Indeed, Baldridge et al. concluded that these two basaltic groups could not have been co-magmatic. In this paper, we suggest an open system AFC model for pigeonite basalt

petrogenesis. The assimilant is lunar anorthositic crust and the r value used is 0.6. While the choice of assimilant composition is difficult to constrain, the modeling demonstrates the feasibility of this model. Derived from text

THE COHERENT BACKSCATTERING OPPOSITION EFFECT Abstract Only **c74**
R. M. Nelson, B. W. Hapke (Pittsburgh Univ., PA.), W. D. Smythe, V. Gharakanian, and P. Herrera *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1061-1062 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

We have measured the opposition effect, the nonlinear surge in reflectance seen in particulate materials as phase angle approaches zero degrees, in a suite of materials of varying particle size and reflectance. These samples were illuminated by linearly and circularly polarized monochromatic radiation at two wavelengths, 0.442 and 0.633 microns. By measuring the linear and circular polarization ratios for each sample, we have found that in highly reflective materials the behavior of the reflected radiation is consistent with the coherent backscattering process which has recently been proposed to explain the opposition surge that is seen in such media. The size and width of the coherent backscattering opposition peak vary as a function of reflectance of the sample. The opposition effect has been observed in particulate materials studied in the laboratory and it is also observed in the radiation reflected from solar system bodies which present a regolith to the earth based observer. The traditional explanation of the opposition effect, the shadow-hiding hypothesis, is that it was caused by the elimination of mutual shadows cast between the regolith grains as the phase angle of the observation became smaller. This shadow-hiding hypothesis, however, is unable to explain the opposition effect seen in highly reflective materials such as magnesium oxide and barium sulfate powders. This is because highly reflective media will multiply scatter the incident radiation between the regolith grains. This causes the shadows to be eliminated. We have measured the angular scattering properties of a suite of materials of different reflectivity. We have observed polarization ratios in reflective particulates that are consistent with coherent backscattering as the principal process which causes the opposition surge. Derived from text

ON MAGNETODYNAMIC EFFECTS INITIATED BY A HIGH-SPEED IMPACT OF A LARGE COSMIC BODY UPON THE EARTH'S SURFACE Abstract Only **c90**
I. V. Nemchinov, P. E. Alexandrov, V. I. Artemiev, V. I. Bergelson, and V. A. Rybakov *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1063-1064 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The impact of a large cosmic body with typical size R approximately = 1 km (mass M approximately = 4-10 Gt for a stony or icy body) moving with velocity V approximately = 50-70 km/s (kinetic energy of the order of 10 exp 21 J or 10 exp 6 Mt of TMT) on the Earth's surface leads to a full vaporization of a body and of a significant part of substance of the upper layers of the Earth and even to the ionization of this vapor cloud. As a result, a hypersonic jet of air and erosion plasma is formed. The kinetic energy E sub J is far above the total energy of the geomagnetic field of the Earth (approximately equivalent to the energy of 100 Mt) and the total mass of a fast-moving part of the jet M sub j approximately = 10 exp 12 kg is far above the mass of atmosphere in the jet expansion cone. Thus, the jet will propagate practically inertially with the constant mean velocity U approximately = 10-20 km/s and even higher. The interaction of this plasma jet with the Earth's magnetic field causes magnetodynamic effects similar to those which are produced by cosmic nuclear explosions but of a larger scale. The preliminary results of experimental and numerical modeling of the plasma jet-magnetosphere interaction are presented. Derived from text

DETERMINATION OF COSMIC BODIES SIZE-VELOCITY DISTRIBUTION BY OBSERVATION OF CURRENT IMPACTS ON MARS Abstract Only **c90**
I. V. Nemchinov, A. A. Perelomova, and V. V. Shuvalov *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1065-1066 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Collisions of cosmic bodies with terrestrial planets involve many physical processes such as deceleration and ablation during their flight through an atmosphere, the impact at a surface accompanied by cratering, melting and evaporation of surface material, generation of shock waves, etc. If body velocity is high enough then a thermal radiation is very important. All these processes on Mars proceed differently than on the other planets because of the low density of its atmosphere. In particular, this leads to the fact that smaller bodies of sizes of the order of 0.1-10 m strike the planet surface without being decelerated and perform some effects which may be detected by equipment placed on a board of artificial satellites, by a network of stations at the surface of Mars and even from the Earth. These observations can be used to determine size-velocity distribution of such bodies in the Solar System. Numerical simulation of the impacts at the surface of Mars have been carried out using two-dimensional gas dynamic code with detailed consideration of the thermal radiative transfer. This work is an extension of our previous paper. We have expanded a range of projectile sizes up to r sub 0 = 100 m. For such a large-scale body, the initial stage of the impact, involving crate ring and ejection of surface material, is very important. Thus, these effects have been taken into account. EFFECTS OF HYDRODYNAMICS AND THERMAL RADIATION IN THE ATMOSPHERE AFTER COMET IMPACTS Abstract Only **c46**
I. V. Nemchinov, M. P. Popova, L. P. Shubadeeva, V. V. Shuvalov, and V. V. Svetsov *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1067-1068 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Radiation phenomena in the atmosphere after impacts of cosmic bodies have special features in comparison with the surface nuclear explosions. First, initial concentration of energy after the impact is lower, and second, a wake after the passage of the meteoroid through the atmosphere has a dramatic effect on the atmospheric flow and radiation transfer. Consequently, scaling laws can not be employed for prediction of the flow in the atmosphere and the light flux on the Earth's surface. If a density of high-velocity impactor is low relative to the ground, as in a case of a comet impact on rocks, a major part of the kinetic energy is converted to internal energy of dense hot vapors. But radiation effects can be essential even for fairly low velocities of the impactor. To clarify this issue we have undertaken calculations of 100-Mt explosions at the Earth's surface caused by small comets with velocities from 10 to 70 km/sec. That is, the initial concentration of energy has been varied. The calculations have shown that for velocities of the comet greater or about 20 km/sec a portion of energy emitted from the fireball exceeds 20% of the total energy of the explosion and this quantity does not change very much with the velocity. Other aspects of this investigation are discussed. Derived from text

The High Resolution Stereo Camera (HRSC) is a planetary imaging system developed by the German Aerospace Research Establishment (DLR) with the involvement of the German Space Industry under the leadership of the German Space Agency (DARA) for the Russian Mars 94 and Mars 96 missions. The same instrument, virtually unmodified, is ideal for imaging

the Moon. If flown on a Lunar Scout spacecraft, the HRSC will be operated so that it will produce data suitable for generation of a global lunar geodetic net, a global stereo image data set (both data sets produced at an orbit altitude of 200 kms approximately) and high resolution stereo imagery of areas of interest to the scientific community from an orbit altitude of 100 kms (resolution is a function of orbit altitude). All data will be digital.

CORE FORMATION IN THE MOON: THE MYSTERY OF THE EXCESS DEPLETION OF Mo, W AND P Abstract Only

H. E. Newsom and S. A. Maehr *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1071-1072 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

We have evaluated siderophile element depletion models for the Moon in light of our improved statistical treatment of siderophile element abundance data and new information on the physics of core formation. If core formation occurred in the Moon at the large degrees of partial melting necessary for metal segregation, according to recent estimates, then a significant inconsistency (not seen in the eucrite parent body) exists in the depletion of the incompatible siderophile elements Mo, W, and P, compared to other siderophile elements in the Moon. The siderophile data, with the exception of Mo, are most consistent with terrestrial initial siderophile abundances and segregation of a very small core in the Moon. Our improved abundance estimates and possible explanations for these discrepancies are discussed.

Avail: CASI HC A01/MF A06

Our recent work on He, Ne, and Ar in Alpine gold samples has demonstrated that gold is extremely retentive for He and could thus, in principle, be used for U/Th-He-4 dating. For vein-type gold from Brusson, Northern Italy, we derived a U/Th-He-4 age of 36 Ma, in agreement with the K-Ar formation age of associated muscovites and biotites. However, in placer gold from the Napf area, Central Switzerland, we observed large excesses of both He-4 and radiogenic Ar-40 (Ar-40 sub rad, defined as Ar-40-295.5-Ar-.36). The gas release systematics indicate two distinct noble gas components, one of which is released below about 800 C and the other one at the melting point of gold (1064 C). We now present results of He and Xe measurements in a 1 g placer gold sample from the river Kruempelgraben, as well as He and Ar data for Brusson vein-type gold and for gold from the Lily Gold Mine, South Africa. We calculate reasonable U/Th-He-4 as well as U-Xe ages based on those gases which are released at approximately 800 C. Probably the low-temperature components represent in-situ-produced radiogenic He and fission Xe, whereas the gases evolving when gold melts have been trapped during gold formation. Therefore, only the low-temperature components are relevant for dating purposes.

HELIUM IN INTERPLANETARY DUST PARTICLES Abstract Only **c90**

A. O. Nier and D. J. Schlutter *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1075-1076 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Helium and neon were extracted from fragments of individual stratosphere-collected interplanetary dust particles (IDP's) by subjecting them to increasing temperature by applying short-duration pulses of power in increasing amounts to the ovens containing the fragments. The experiment was designed to see whether differences in release temperatures could be observed which might provide clues as to the asteroidal or cometary origin of the particles. Variations were observed which show promise for elucidating the problem.

GEOLOGIC MAPPING OF NORTHERN ATLA REGIO ON VENUS: PRELIMINARY DATA Abstract Only

A. M. Nikishin and G. A. Burba (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1077-1078 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

The Northern part of Atla Regio within the frame of C1-formate Magellan photo map 15N197 was mapped geologically at scale 1:8,000,000. This is a part of Russia's contribution into C1 geologic mapping efforts. The map is reproduced here being reduced about twice. The map shows that the Northern Atla area is predominantly a volcanic plain with numerous volcanic features: shield volcanoes, domes and hills with various morphology, corona-like constructions, radar bright and dark spots often with flow-like outlines. Relatively small areas of tessera occurred in the area are mainly semi-flooded with the plain material. Tesserae are considered to be the oldest terrains within the map sheet. There are many lineated terrains in the region. They are interpreted as the old, almost-buried tesserae (those with crossed lineaments) or partly buried ridge belts (those with parallel lineaments). These lineated terrains have an intermediate age between the young volcanic plains and the old tessera areas. Two prominent high volcanic shields are located within the region - Ozza Mons and Sapas Mona. The most prominent structure in Northern Atla is Ganis Chasma rift. The rift cuts volcanic plain and is considered to be under formation during approximately the same time with Ozza Mons shield. Ganis Chasma rift valley is highly fractured and bounded with fault scarps. Rift shoulder uplifts are typical for Ganis Chasma. There are few relatively young volcanic features inside the rift valley. The analysis of fracturing and rift valley geometry shows the rift originated due to 5-10 percent crustal extention followed by the crustal subsidence. The age sequence summary for the main terrain types in the region is (from older to younger ones): tesserae; lineated terrains with crossed lineaments; lineated terrains with parallel lineaments; volcanic plains; and prominent volcanic shields and Ganis Chasma rift valley. The geologic structure of Atla Regio as it appeared now with the Magellan high resolution images is very close to that of Beta Regio. Such conclusion coincide with the earlier ones based on the coarser data.

BETA REGIO RIFT SYSTEM ON VENUS: GEOLOGIC INTERPRETATION OF MAGELLAN IMAGES

A. M. Nikishin, N. N. Bobina (Academy of Sciences, USSR, Moscow.), V. K. Borozdin (Academy of Sciences, USSR, Moscow.), and G. A. Burba (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1079-1080 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Magellan SAR images and altimetric data were used to produce a new geologic map of the Northern part of Beta Regio within the frames of C1-30N279 mapsheet. It was part of our contributions into C1-formate geologic mapping efforts. The original map is at 1:8,000,000 scale. The rift structures are typical for Beta Regio on Venus. There are many large uplifted tessera areas on Beta upland. They occupy areas of higher topography. These tessera are partly burried by younger volcanic cover of plain material. These observations show that Beta upland was formed mainly due to lithospheric tectonical uplifting, and only partly was constructed by volcanic activity. A number of rift valleis traverse Beta upland and spread to the surrounding lowlands. The largest rift crosses Beta N to S. Typical width of rifts is 40 to 160 km. Rift valleis in this region are structurally represented by crustal grabens and half-grabens. There are symmetrical and asymmetrical rifts. A lot of them have shoulder uplifts with the relative high up to 0.5-1 km and width 40 to 60 km. Preliminary analysis of the largest rift valley structural cross-sections leads to the conclusion that it originated due to a 5-10 percent crustal extension. The prominent shield volcano - Theia Mons - is located at the center of Beta rift system. It could be considered as the surface manifestation of the upper mantle hot spot. Most of the rift belts are located radially to Theia Mons. The set of these data leads to conclusion that Beta rift system has

an 'active-passive' origin. It was formed due to the regional tectonic lithospheric extension. Rifting was accelerated by the upper mantle hot spot located under the center of passive extension (under Beta Regio).

LARGEST IMPACT FEATURES ON VENUS: NON-PRESERVED OR NON-RECOGNIZABLE? Abstract Only
Olga V. Nikolaeva *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1083-1084 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Conventional explanation of a lack of impact craters with diameters greater than 300 km on Venus is that they formed during the intense bombardment era and had lunar-like morphology, but they are not preserved now because of rapid viscous relaxation of their topograpy and/or high endogenous reworking of surface. Other explanation invokes failure to recognize these larger craters because of their non-lunar-like morphology from the moment of formation, since larger gravity of Venus relatively to the Moon results in that largest craters on Venus may form within the mass of shock melted material while comparably sized lunar craters would be still almost 'dry'. To test this hypothesis, morphologies and rim-crest diameters of the largest peak-ring and Orientale-type basins and all larger impact features on Moon, Mercury, Mars, and Venus were compiled and compared to rim crest diameters of model craters with different melt volume/transient-cavity volume ratios. Results show that the final diameters of model craters formed at depth of melting about twice of transient cavity depth correspond to changeover from a planet-similar morphology of all the smaller basins on any terrestrial planet to a planet-specific morphology of all the larger basins on the Moon, Mercury, and Mars. On Venus, these largest impact features are not found and instead, a Venus-specific morphology of the largest concentric coronae appears in this size range. The coronae were suggested to form over sites of mantle upwelling and modified by subsequent volcanism and gravitational relaxation. The results here suggest that mantle upwelling - the first and necessary step of the corona formation models - may be induced by impact event (as a result of transient cavity collapse) and operated under cover of hot, slowly cooled impact melt in the areas of thinned crust and/or thermally active regions.

The recent exposure histories of carbonaceous chondrites have been investigated using cosmogenic radionuclides. Our results may indicate a clustering of exposure ages of C1 and C2 chondrites into two peaks, 0.2 My and 0.6 My, perhaps implying two collisional events of Earth-crossing parent bodies. Among carbonaceous chondrites are some having short exposure ages which Mazor et al. hypothesized cluster into a small number of families. This hypothesis is based on spallogenic Ne-21 exposure ages, which in some instances are difficult to determine owing to the large amounts of trapped noble gases in carbonaceous chondrites. Also, since Ne-21 is stable, it integrates a sample's entire exposure history, so meteorites with complex exposure histories are difficult to understand using exclusively Ne-21. Cosmogenic radionuclides provide an alternative means of determining the recent cosmic ray exposure duration. To test the hypothesis of Mazor et al. we have begun a systematic investigation of exposure histories of Antarctic and non-Antarctic carbonaceous chondrites especially C2s.

IDENTIFICATION OF AN INTERSTELLAR OXIDE GRAIN FROM THE MURCHISON METEORITE BY ION IMAGING Abstract Only c90
L. R. Nittler, R. M. Walker, E. Zinner, P. Hoppe (Bern Univ., Switzerland.), and R. S. Lewis (Chicago Univ., IL.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1087-1088 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

We report here the first use of a new ion-imaging system to locate a rare interstellar aluminum oxide grain in a Murchison acid residue. While several types of carbon-rich interstellar grains, including graphite, diamond, SiC, and TiC, have previously been found, isotopically anomalous interstellar oxide grains have proven more elusive. We have developed an ion imaging system which allows us to map the isotopic composition of large numbers of grains relatively quickly and is, thus, ideally suited to search for isotopically exotic subsets of grains. The system consists of a PHOTOMETRICS CCD camera coupled to the microchannel plate/fluorescent screen of the WU modified CAMECA IMS-3F ion microprobe. Isotopic images of the sample surface are focused on the CCD and digitized. Subsequent image processing identifies individual grains in the images and determines isotopic ratios for each. For the present work, we have imaged in O-16 and O-18; negligible contributions of (17)OH(-) and (16)OH2(-) signals to the O-18 signal allow the use of low mass resolution, simplifying the measurements. Repeated imaging runs on terrestrial corundum particles showed that the system measures isotopic ratios reproducibly to about +/- 40%. Each imaging run took about six minutes to complete, and for this study there were on average 5-15 grains in each image. We have conducted imaging searches in 2-4 micron size separates of both Orgueil and Murchison.

FRAGMENTS OF ANCIENT LUNAR CRUST: FERROAN NORITIC ANORTHOSITES FROM THE DESCARTES REGION OF THE MOON Abstract Only
M. D. Norman, C. Alibert (Australian National Univ., Canberra.), and M. T. McCulloch (Australian National Univ., Canberra.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1089-1090 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Noritic anorthosite clasts from breccia 67016 have bulk compositions similar to that of the upper crust of the Moon and petrogenetic affinities with pristine ferroan anorthosites. Rb-Sr and Sm-Nd isotopic compositions of mineral separates from one of these clasts suggest very old (greater than or = 4.4 Ga) ages, but interpretation of these data is complicated by the multi-stage history of the clasts which involved magmatic crystallization, brecciation, subsolidus recrystallization, and sulfide metasomatism. These clasts record some of the earliest events on the Moon, including early crust formation, accretionary bombardment, and degassing of the lunar interior. Modal analyses of these clasts show they are now composed of about 70 percent plagioclase, 28 percent pyroxene, 2 percent troilite, and minor amounts of ilmenite and chromite. No metallic iron, phosphates, or other trace phases were observed. Olivine is very rare, occurring only as relicts within secondary troilite+pyroxene intergrowths which may reflect reaction of olivine with sulfurous vapors. PIXE proton microprobe analyses of the sulfides show that the metasomatism was accompanied by enrichments of Cu, Zn, Ni, Se, and Sb. The clasts have been only mildly shocked since the observed texture was established. Major and minor element mineral compositions are very homogeneous and strikingly similar

to those of pristine ferroan anorthosites. Pyroxene compositions indicate equilibration temperatures of 850-900 C. Except for the sulfide and chalcophile element metasomatism, these clasts appear to be essentially monomict and probably represent a noritic member of the ferroan anorthosite suite. Their low Ni contents and Ni/Co ratios are consistent with the interpretation of these clasts as igneous rocks which have escaped mixing with meteoritic material. Derived from text

VOLATILITY IN THE LUNAR CRUST: TRACE ELEMENT ANALYSES OF LUNAR MINERALS BY PIXE PROTON MICROPROBE Abstract Only

M. D. Norman, W. L. Griffin (Commonwealth Scientific and Industrial Research Organization, North Ryde, Australia.), and C. G. Ryan (Commonwealth Scientific and Industrial Research Organization, North Ryde, Australia.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1091-1092 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

In situ determination of mineral compositions using microbeam techniques can characterize magma compositions through mineral-melt partitioning, and be used to investigate fine-grained or rare phases which cannot be extracted for analysis. Abundances of Fe, Mn, Sr, Ga, Zr, Y, Nb, Zn, Cu, Ni, Se, and Sb were determined for various mineral phases in a small number of lunar highlands rocks using the PIXE proton microprobe. Sr/Ga ratios of plagioclase and Mn/Zn ratios of mafic silicates show that the ferroan anorthosites and Mg-suite cumulates are depleted in volatile lithophile elements to about the same degree compared with chondrites and the Earth. This links the entire lunar crust to common processes or source compositions. In contrast, secondary sulfides in Descartes breccia clasts are enriched in chalcophile elements such as Cu, Zn, Ni, Se, and Sb, and represent a potential resource in the lunar highlands. The chemical compositions of microscopic glasses produced during meteoroid impacts on the lunar surface provide information regarding the various fractionation processes which accompany these events. To learn more about these fractionation processes, we studied the compositions of submicrometer glass spheres from two Apollo 17 sampling sites using electron microscopy. The majority of the analyzed glasses show evidence for varying degrees of impact induced chemical fractionation. Among these are HASP glasses (High-Al, Si-Poor) which are believed to represent the refractory residuum left after the loss of volatile elements (e.g. Si, Fe, N) from the precursor material. In addition to HASP-type glasses, we also observed a group of VRAP glasses (volatile-rich, Al-poor) that represent condensates of vaporized volatile constituents and are complementary to the HASP compositions. High-Ti glasses were also found during the course of the study, and are documented here for the first time.

THE Sm-(146,147)-Nd-(142,143) FORMATION INTERVAL FOR THE LUNAR MANTLE AND IMPLICATIONS FOR LUNAR EVOLUTION Abstract Only

L. E. Nyquist, C.-Y. Shih (Lockheed Engineering and Sciences Co., Houston, TX.), H. Wiesmann (Lockheed Engineering and Sciences Co., Houston, TX.), and B. M. Bansal (Lockheed Engineering and Sciences Co., Houston, TX.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1095-1096 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Small anomalies in the isotopic abundance of Nd-142 have been measured for two A17 high-Ti basalts, ilmenite basalt 12056, olivine-pigeonite basalt 12039, feldspathic basalt 12038, and two KREEP basalts. These anomalies correlate with Sm-147/Nd-144 for the basalt source regions as calculated from initial Nd-143/Nd-144 ratios in the basalts, and are interpreted to be from decay of Sm-146 (t sub 1/2 = 103 Ma) in distinct lunar mantle reservoirs. A three-stage model for evolution of Nd-143/Nd-144 and Nd-142/Nd-144 yields reservoir Sm-147/Nd-144 ratios which, with the Nd-142/Nd-144 ratios in the basalts, form a 'mantle isochron' giving a lunar mantle formation interval of 94+2230 Ma (2c(rho)). Calculated reservoir Sm/Nd ratios are in the range expected from some earlier models of basalt petrogenesis. The isochron value of Nd-142/Nd-144 at Sm-147/Nd-144 sub CHUR = 0.1967 is within error limits of the average Nd-142/Nd-144 measured for an L6 chondrite, an H5 chondrite, and the Orgueil carbonaceous chondrite. Evolution of Nd-143 and Nd-142 for high-Ti basalt 70135 was modeled precisely, starting from chondritic relative REE and Nd-isotopic abundances and using the initial (Sm-146/Sm-144) sub 0 ratio inferred from a previous study of angrite LEW86010 as the initial solar system value of this parameter. We infer that the initial Sm/Nd ratio in precursor lunar materials was very nearly chondritic (within approximately 8 percent) prior to lunar differentiation. Derived from text

GONIOSPECTROMETRIC PROPERTIES OF A WHITE STANDARD Abstract Only c25

A. Oehler and A. Dummel *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1097-1098 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Reflection spectroscopy is one of the fundamental tools in planetary remote sensing. Most of the laboratory work is done in terms of bidirectional reflectance R in the wavelength range of reflected sunlight (250 nm - 2500 nm). Bidirectional reflectance R is defined as the radiance of a surface relative to the radiance of an ideal Lambertian reflector, identically illuminated (radiance coefficient). For quantitative laboratory work the absolute scale of R has to be known. In addition, for many purposes it is necessary to know the dependence of R from phase angle for a large range of geometries. In many cases, this can only be achieved if the goniospectrometric properties of the white standard that is used are known with high precision. For a long time Halon has been used as a white standard by most laboratories. Because Halon is no more available we have now analyzed the goniospectrometric properties of Spectralon SRS-99 with the DLR-goniospectrometer. Derived from text

CHARACTERIZATION OF MINNESOTA LUNAR SIMULANT FOR PLANT GROWTH Abstract Only c54

James P. Ogiesby, Willard L. Lindsay, and Willy Z. Sadeh *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1099 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Processing of lunar regolith into a plant growth medium is crucial in the development of a regenerative life support system for a lunar base. Plants, which are the core of such a system, produce food and oxygen for humans and, at the same time, consume carbon dioxide. Because of the scarcity of lunar regolith, simulants must be used to infer its properties and to develop procedures for weathering and chemical analyses. The Minnesota Lunar Simulant (MLS) has been identified to date as the best available simulant for lunar regolith. Results of the dissolution studies reveal that appropriately fertilized MLS can be a suitable medium for plant growth. The techniques used in conducting these studies can be extended to investigate the suitability of actual lunar regolith as a plant growth medium. Dissolution experiments were conducted using the MLS to determine its nutritional and toxicity characteristics for plant growth and to develop weathering and chemical analysis techniques. Two weathering regimes, one with water and one with dilute organic acids simulating the root rhizosphere microenvironment, were investigated. Elemental concentrations were measured using inductively-coupled-plasma (ICP) emission spectrometry and ion chromatography (IC). The geochemical speciation

model, MINTEQA2, was used to determine the major solution species and the minerals controlling them. Acidification was found to be a useful method for increasing cation concentrations to meaningful levels. Initial results indicate that MLS weathers to give neutral to slightly basic solutions which contain acceptable amounts of the essential elements required for plant nutrition (i.e., potassium, calcium, magnesium, sulfur, zinc, sodium, silicon, manganese, copper, chlorine, boron, molybdenum, and cobalt). Elements that need to be supplemented include carbon, nitrogen, and perhaps phosphorus and iron. Trace metals in solution were present at nontoxic levels. Derived from text

DYNAMICS OF LARGE SCALE IMPACTS ON VENUS AND EARTH Abstract Only

John D. OKeefe and Thomas J. Ahrens *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1101-1102 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Large scale impacts are a key aspect of the accretion and growth of the planets, the evolution of their atmospheres, and the viability of their life forms. We have performed an extensive series of numerical calculations that examined the mechanics of impacts over a broad range of conditions and are now extending these to account for the effects of the planetary atmosphere. We have examined the effects of large scale impacts in which the trapping and compression of an atmosphere during impact is a significant factor in the transfer of energy to the atmosphere. The various energy transfer regimes and where conventional drag and trapping and subsequent compression of atmosphere between the bolide and planetary surface are significant are shown. TAMBO QUEMADO: EXTRAORDINARY CONCENTRATIONS OF REE AND REFRACTORY TRACE ELEMENTS CAUSED BY ARTIFICIAL HEATING Abstract Only c25

E. Olsen, I. Hutcheon (California Inst. of Tech., Pasadena.), and C. Moore (Arizona State Univ., Tempe.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1103-1104 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Buchwald examined samples of the IIIB iron Tambo Quemado (TAMQ) cut from the 130 kg main mass. He determined it had been artificially heated, at some time prior to being reported, in an attempt to obtain metal from it. Although the Widmanstatten structure appears relatively unaffected under macroscopic examination, microscopic study of etched sections reveals the effect of the heating. Taenite and plessite area boundaries are indistinct due to high temperature diffusion. Schreibersite, once present in significant amounts, has been melted. Schreibersites in the interior have resolidified in fine-grained eutectic textures surrounded by dark-etching metal rims supersaturated with phosphorus. Buchwald states that phosphate minerals were probably present originally, because graftonite, and its polymorph sarcopside (both essentially Fe3(PO4)2), are common in irons of the IIIB groups. Based on his metallographic study Buchwald estimates TAMQ was heated to 1000 C for about one hour. An interior sample from TAMQ was examined in order to determine what effect this unintended heating 'experiment' had upon the phosphate phases. Derived from text

MODELLING THE GRAVITY AND MAGNETIC FIELD ANOMALIES OF THE CHICXULUB CRATER Abstract Only c46

C. Ortiz Aleman, M. Pilkington (Geological Survey of Canada, Ottawa, Ontario.), A. R. Hildebrand (Geological Survey of Canada, Ottawa, Ontario.), W. R. Roest (Geological Survey of Canada, Ottawa, Ontario.), R. A. F. Grieve (Geological Survey of Canada, Ottawa, Ontario.), and P. Keating (Geological Survey of Canada, Ottawa, Ontario.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1105-1106 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The approximately 180-km-diameter Chicxulub crater lies buried by approximately 1 km of sediment on the northwestern corner of the Yucatan Peninsula, Mexico. Geophysical, stratigraphic and petrologic evidence support an impact origin for the structure and biostratigraphy suggests that a K/T age is possible for the impact. The crater's location is in agreement with constraints derived from proximal K/T impact-wave and ejecta deposits and its melt-rock is similar in composition to the K/T tektites. Radiometric dating of the melt rock reveals an age identical to that of the K/T tektites. The impact which produced the Chicxulub crater probably produced the K/T extinctions and understanding the now-buried crater will provide constraints on the impact's lethal effects. The outstanding preservation of the crater, the availability of detailed gravity and magnetic data sets, and the two-component target of carbonate/evaporites overlying silicate basement allow application of geophysical modeling techniques to explore the crater under most favorable circumstances. We have found that the main features of the gravity and magnetic field anomalies may be produced by the crater lithologies. Author

SELF DIFFUSION OF ALKALINE-EARTH IN Ca-Mg-ALUMINOSILICATE MELTS: EXPERIMENTAL IMPROVEMENTS ON THE DETERMINATION OF THE SELF-DIFFUSION COEFFICIENTS Abstract Only c25

O. Paillat and G. J. Wasserburg *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1107-1108 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Experimental studies of self-diffusion isotopes in silicate melts often have quite large uncertainties when comparing one study to another. We designed an experiment in order to improve the precision of the results by simultaneously studying several elements (Mg, Ca, Sr, Ba) during the same experiment thereby greatly reducing the relative experimental uncertainties. Results show that the uncertainties on the diffusion coefficients can be reduced to 10 percent, allowing a more reliable comparison of differences of self-diffusion coefficients of the elements. This type of experiment permits us to study precisely and simultaneously several elements with no restriction on any element. We also designed an experiment to investigate the possible effects of multicomponent diffusion during Mg self-diffusion experiments by comparing cases where the concentrations of the elements and the isotopic compositions are different. The results suggest that there are differences between the effective means of transport. This approach should allow us to investigate the importance of multicomponent diffusion in silicate melts. ORTHOPYROXENES AS RECORDERS OF DIOGENITE PETROGENESIS: MAJOR AND MINOR ELEMENT SYSTEMATICS Abstract Only c25

J. J. Papike, M. N. Spilde, G. W. Fowler, and C. K. Shearer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1109-1110 (For primary document see N94-20636 05-91)
(Grant NAG9-497)
Avail: CASI HC A01/MF A06

As a part of our research to better understand magmatic processes in the Eucrite Parent Body, we have initiated an ambitious program of study of major, minor and trace elements in orthopyroxene from diogenites. This paper reports preliminary results for major and minor elements in orthopyroxenes for a suite of 13 diogenites: Aioun El Atrouss, ALH 84001, ALH A 77256, EET 87530, Ellemeet, Garland, Ibbenburen, Johnstown, Manegoan, peckelsheim, Roda, Shalka, and Tatahouine. A companion paper by Shearer et al. reports new trace element data for ALH 84001, ALH A 77256, Ibbenburen, and Tatahouine. We have presently collected over 800 high quality pyroxene microprobe analyses for Si, Al, Ca, Na, Mn, Fe, Mg, Cr, and Ti. The chemical systematics observed for these orthopyroxenes reflect original magmatic mineral/melt partitioning plus later trapped liquid/mineral equilibration, subsolids, exsolution, and mineral/mineral metamorphic reactions. We have therefore avoided, at this point, any attempt to use statistical analysis to group (e.g. factor or cluster analysis) these orthopyroxenes chemically. Derived from text

STRUCTURAL EVIDENCE FOR REORIENTATION OF MIRANDA ABOUT A PALEO-POLE Abstract Only

R. Pappalardo and R. Greeley *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1111-1112 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Two structural arguments support the premise that Miranda has reoriented with respect to Uranus over its geologic history. Orientations of major extensional and compressional features are consistent with a major satellite reorientation similar to that previously suggested based on cratering asymmetry. Furthermore, structures within Elsinore Corona provide supporting evidence that this reorientation took place about a paleo-pole located near (-75 deg, 80 deg), suggesting a second minor reorientation of Miranda.

FORMATION AND EVOLUTION OF RADIAL FRACTURE SYSTEMS ON VENUS Abstract Only
E. A. Parfitt and James W. Head *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1113-1114 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A survey of approximately 90 percent of the surface of Venus using Magellan data has been carried out to locate all radial fracture systems and to assess their association with other features such as volcanic edifices and coronae. Squyres et al. and Stofan et al. have discussed the association of radial fracture features in relation to coronae features, our approach was to assess the associations of all of the fracture systems. These fracture systems have two broad types of form - some fracture systems are associated with updomed topography, radiate from a point and have relatively uniform fracture lengths while others have a wider range of fracture lengths and radiate from the outer edge of a central caldera. Squyres et al. and Stofan et al. have interpreted both types of feature as reflecting tectonic fracturing resulting from uplift of the surface as a mantle plume impinges upon the crust. While it is true that a number of features are related to uplift and that such uplift will induce stresses consistent with radial fracturing, we explore the possibility that these fractures are not exclusively of tectonic origin. Purely tectonic fracturing will tend to generate a few main fractures/faults along which most of the stresses due to uplift will be accommodated leading to the triple-junction form common for terrestrial updoming. Though this type of feature is observed on Venus (e.g., feature located at 34S86), the majority of radial fracture systems display much more intensive fracturing than this through a full 360 degrees; this is difficult to explain by purely tectonic processes. The association of many of the fractures with radial lava flows leads us to interpret these fractures as reflecting dike emplacement: the form of the fractures being consistent with primarily vertical propagation from the head of a mantle plume. In the case of the second type of fracture system (those radiating from a central caldera), an even stronger case can be made that the fractures are not of tectonic origin. These features are not as commonly associated with updoming of the surface and where they are, the fractures extend out well beyond the edge of the topographic rise - an observation which is not consistent with the fractures being of tectonic uplift origin. Furthermore the fractures have a distribution of lengths (many short, fewer long) which is characteristic of dike swarms, and show direct associations with calderas and lava flows consistent with a volcanic origin. In addition, the longest fractures have a radial pattern only close to the center of the system but bend with distance to align themselves with the regional stress field - this behavior is very difficult to explain on purely tectonic grounds but is a pattern commonly seen for terrestrial dikes. For these reasons, we argue that many, if not the majority, of radial fracture systems found on Venus are the surface reflection of dike swarms, those associated with positive topography reflecting vertical emplacement and those radiating from calderas reflecting lateral propagation.

THERMAL AND RHEOLOGICAL CONTROLS ON MAGMA MIGRATION IN DIKES: EXAMPLES FROM THE EAST RIFT ZONE OF KILAUEA VOLCANO, HAWAII Abstract Only **c46**
E. A. Parfitt, L. Wilson, and H. Pinkerton (Lancaster Univ., England.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1115-1116 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Long-lived eruptions from basaltic volcanoes involving episodic or steady activity indicate that a delicate balance has been struck between the rate of magma cooling in the dike system feeding the vent and the rate of magma supply to the dike system from a reservoir. We describe some key factors, involving the relationships between magma temperature, magma rheology, and dike geometry that control the nature of such eruptions.

CONSTRAINTS ON THE RATE OF DISCHARGE AND DURATION OF THE MANGALA VALLES FLOOD Abstract Only
T. J. Parker and D. S. Gorsline *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1117-1118 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Interest in Mangala Valles remains high within the planetary science community. This is justified because the survey mission images provide us with nearly complete coverage of the system at high resolution. Upcoming high resolution topography from the Mars Observer Laser Altimeter will enable the application of flood discharge models with an unprecedented level of detail. Previous work on the Mangala Valles problem has relied on the available low resolution topography. This has limited the ability of workers to constrain discharge calculations to only within several-order-of-magnitude estimates. Local determinations of channel depths via shadow length measurements and photoclinometric profiling are much more accurate, but can only be applied to steep slopes (and/or low sun elevations) in the case of shadow measurements, or across relatively short distances (to avoid changes in albedo along asymmetric photoclinometric profiles). We are taking stereo parallax measurements from medium resolution Viking Orbiter images, which provide a valuable intermediate check of the topography between those measurements made thus far and the upcoming Mars Observer data. The images used are from orbits 034A and 637A, and cover Mangala Valles from the source graben in Memnonia Fossae to the beginning of the bifurcated reach (at 9.5 deg lat., 151.5 deg lon.). These images are about 300 m/pixel and 250 m/pixel, respectively. Both sets of images were orthographically projected to 250 m/pixel. The separation angle between left-right pairs is approximately 52 degrees. This results in a vertical accuracy on the order of plus or minus 260 m. Though this is still somewhat coarse, the channel relief is clearly resolved. Preliminary profiles across Mangala Valles and the large topographic ridge to the east are shown on the following page. An east-west regional tilt that resulted from slight scaling differences in the digital data has been 'removed' by visually estimating a regional datum on the stereo pairs. North-south variations in scale have not yet been adjusted for, so the zero datum for each profile was simply taken to be the high water line of the channel itself. Our depth measurement for the source breach of about 750 m agrees reasonably well with values of 700-1000 m determined from shadow measurements.

MIXING OF A CHEMICALLY BUOYANT LAYER AT THE TOP OF A THERMALLY CONVECTING FLUID: IMPLICATIONS FOR MANTLE DYNAMICS WITH APPLICATION TO VENUS Abstract Only
E. M. Parmentier, P. C. Hess, and C. Sotin (Paris Univ., France.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1119-1120 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Partial melting to generate the crust of a planet can create a buoyant residual layer at the top of the mantle which may have important implications for episodic planetary evolution. However, the rate of mixing of such a chemically buoyant layer with a thermally convecting mantle is an important unresolved question. Except for a few laboratory and numerical studies designed to address questions related to convection in the Earth's mantle, previous studies have generally treated on the mixing of passive tracers. The inhibiting role of chemical buoyancy on mixing is intuitively obvious but not fully understood quantitatively. In this study, we examine the dynamics

of an intrinsically buoyant fluid layer at the top of a deeper, thermally convecting, infinite Prandtl number fluid that is heated from below.

ABUNDANCE AND COMPOSITION OF SOLAR KR IN THE H3-H6 CHONDRITE ACFER111 Abstract Only **c25**
A. Pedroni *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1121-1122 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

He/Ne, Ne/Ar, and Ar/Kr abundance ratios of solar gases extracted by stepped heating, stepped oxidation, and stepped etching of lunar and meteoritic regoliths are significantly lower than ratios measured directly or predicted by model estimates. Of these, the differences in the He/Ne and Ne/Ar ratios are explained to be owing to diffusive fractionation losses from the host minerals. In contrast, it remains controversial if the Ar/Kr and Kr/Xe ratios were fractionated prior to or after the implantation of the gases into the minerals. In the H3-H6 chondritic regolith breccia ACFER 111, measured He/Ne and Ne/Ar ratios appear to be of nearly unfractionated solar composition. The Ar/Kr ratio of ACFER 111, might thus be also unfractionated. We examined by stepped etching a metal sample of ACFER 111 and obtained an average solar 36Ar/84Kr = 3150 plus or minus 300 which is in agreement with the model predictions. The isotopic composition of solar Kr was observed to change in the course of the etching in a way very similar to that report for lunar ilmenites by the Zurich group. This can be interpreted as a change of the mixing ratio of Solar Wind (SW) and Solar Energetic Particles (SEP). The isotopic composition of the SEP component obtained from our Kr data, however, is distinct from that reported by the Zurich group. Derived from text

FIRST DISCOVERY OF THE ORGANIC MATERIALS IN DEEP-SEA IRON COSMIC SPHERULE Abstract Only **c25**
Peng Hanchang and Xu Peicang (Xian Inst. of Geology and Mineral Resources, China.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1123-1124 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The dust impact mass analyzer (PUMA) carried by the spacecraft Vega 1, Vega 2 and Giotto has provided the first direct measurements of the physical and chemical properties of cometary dust. The results indicate that most of the cometary dust particles are rich in light elements such as H, C, N, and O, suggesting the validity of models that describe the cometary dust as including organic material. Up to now, there were none found with the organic material from the deep-sea cosmic spherules. We have determined this from the deep-sea iron cosmic spherules collected from the North Pacific. An iron cosmic spherule (382 microns in diameter) was determined by the Laser Raman Microprobe. Derived from text

Engrand (Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Orsay, France.), Michel Maurette (Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Orsay, France.), G. Kurat (Naturhistorisches Museum, Vienna, Austria.), and Th. Presper (Naturhistorisches Museum, Vienna, Austria.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1125-1126 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Antarctic micrometeorites (AMM's) have similarities (but also differences) with primitive meteorites, such as unequilibrated mineral assemblages. To further assess such similarities, we have measured the carbon content of micrometeorites and meteorites (Orgueil and Murchison), as determined in a random selection of micrometer-size crushed grain, with an analytical transmission electron microscope. Such analyses yield the C/O atomic ratio, the major and minor elements contents, and the textural features of the grains on a scale of approx. equal to 100 nanometers. An important proportion of micrometeorites from both the 100-400 micron and the 50-100 micron size fractions contains much more carbon than CI chondrite Orgueil. The average C-content of all micrometeorites in these two size fractions amount to approximately 1.8 x CI, and approximately 0.8 x CI, respectively (CI refers to the bulk C-content of Orgueil, of about 3.5 percent by weight). Carbon is usually not homogeneously distributed in the micrometeorite but is concentrated in C-rich grains. So far, most of these grains are amorphous, and seem to be associated with an oxidized Fe-rich phase (possibly a variety of 'dirty' magnetite). About 5 percent of them have the composition of 'COPS', a phase additionally enriched in O, P, and S.

LAMELLAR OLIVINE IN THE DIVNOE ACHONDRITE: EVIDENCE FOR HIGH-PRESSURE EXSOLUTION? Abstract Only **c25**
M. I. Petaev *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1127-1128 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The olivine-rich Divnoe achondrite contains numerous large olivine grains which have a lamellar or banded appearance in back-scattered electron images, caused by minor compositional differences. One such grain, viewed in transmitted light, displays a system of lamellae with the same orientation and scale as the compositional banding. The only process known to produce such structure and chemical variability in olivine grains is high-pressure transformations between alpha-, beta- and gamma-olivines, but in other meteorites and in experimental products the structure is approximately 100 times finer than the Divnoe lamella. Author

OPAQUE-RICH LITHOLOGY IN THE DIVNOE ACHONDRITE: PETROLOGY AND ORIGIN Abstract Only **c90**
M. I. Petaev *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1129-1130 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

An opaque-rich lithology (ORL) makes up to approximately 9 vol. percent of the Divnoe achondrite. It is characterized by enrichment of troilite and pyroxene, compared to the bulk Divnoe, and by the presence of tiny remnants of olivine in low-CA pyroxene and low minor element concentrations in pyroxene. The ORL was formed by local reaction between gaseous sulfur and olivine in the Divnoe. The Divnoe meteorite is an olivine-rich achondrite with subchondritic chemistry and mineralogy. It has a granoblastic coarse-grained olivine groundmass (CGL: coarse-grained lithology) with relatively large (2-10 mm) poikilitic patches (PP) of pyroxene and, rarely, plagioclase. The groundmass also contains an opaque-rich fine-grained lithology (ORL) which comprises approximately 9 vol. percent of the meteorite, displays reaction boundaries with the groundmass, and differs in mineral chemistry from it. Numerous micron- to mm-thick veins of troilite and, rarely, metal cross all the lithologies found in the meteorite. The Divnoe itself appears to represent a sample of an igneous source region. CHAUNSKIJ: THE MOST HIGHLY METAMORPHOSED, SHOCK-MODIFIED AND METAL-RICH MESOSIDERITE Abstract Only **c90**
M. I. Petaev, R. S. Clarke, Jr. (Smithsonian Institution, Washington, DC.), E. J. Olsen (Chicago Univ., IL.), E. Jarosewich (Smithsonian Institution, Washington, DC.), A. M. Davis (Chicago Univ., IL.), I. M. Steele (Chicago Univ., IL.), M. E. Lipschutz (Purdue Univ., West Lafayette, IN.), M.-S. Wang (Purdue Univ., West Lafayette, IN.), R. N. Clayton (Chicago Univ., IL.), and T. K. Mayeda (Chicago Univ., IL.) et al *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1131-1132 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The 1990 g Chaunskij meteorite was found in 1985 and classified as an anomalous ungrouped iron. It contains approximately 10 vol. percent mono- and polymineralic troilite-phosphate-silicate inclusions, microns to centimeters in size. We proposed its affinity with mesosiderites; here we

present mineralogical, chemical, and isotopic data establishing that Chaunskij is the most highly metamorphosed, shock-modified, and metal-rich of the mesosiderites. The most striking manifestation of metamorphism in Chaunskij is the presence in it of a cordierite-bearing assemblage substituting for basalt lithology. Derived from text

SPECTRAL REFLECTANCE STUDIES OF THE HUMORUM BASIN REGION Abstract Only
C. A. Peterson, B. R. Hawke, P. G. Lucey, G. J. Taylor, D. T. Blewett, and P. D. Spudis (Lunar and Planetary Inst., Houston, TX.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1133-1134 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A portion of the mare-bounding (MB) ring of Humorum Basin is composed of pure anorthosite while other parts of the ring are composed of noritic anorthosite. An episode of mare volcanism emplaced basaltic units in the region northwest of the MB ring after the Humorum impact event. Subsequently, large impacts emplaced a veneer of highlands material atop the basalt flows. Some mare material could have been mixed with this highlands debris either by local mixing by secondary craters or by vertical mixing. Spectra for most other highlands units in the region indicate a noritic anorthosite lithology. Spectra of mare basalts in Mare Humorum and nearby mare flooded craters show relatively deep absorption bands due to the presence of abundant high-Ca pyroxene. An analysis of spectra for a small number of craters in the highlands west of the outer ring of Humorum reveals the presence of high-Ca pyroxene. This suggests the possible presence of an extensive gabbroic province. Author

VENUS MAGMATIC AND TECTONIC EVOLUTION Abstract Only
R. J. Phillips and V. L. Hansen (Southern Methodist Univ., Dallas, TX.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1135-1136 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Two years beyond the initial mapping by the Magellan spacecraft, hypotheses for the magmatic and tectonic evolution of Venus have become refined and focused. We present our view of these processes, attempting to synthesize aspects of a model for the tectonic and magmatic behavior of the planet. The ideas presented should be taken collectively as an hypothesis subject to further testing. The quintessence of our model is that shear and buoyancy forces in the upper boundary layer of mantle convection give rise to a spatially and temporally complex pattern of strain in a one-plate Venusian lithosphere and modulate the timing and occurrence of magmatism on a global basis. Avail: CASI HC A01/MF A06

In our analyses, we utilize a microdrilling technique that removes 40 to 100 micron diameter cores from mineral grains in thin sections analyzed by microprobe. The cores are then analyzed by INAA using the technique of Lindstrom. Three eucrites were selected for application of this analytical technique: monomict breccias Pasamonte and Stannern and unbrecciated EET90020. Pasamonte is among the most unequilibrated of the eucrites on the basis of zoning in pyroxenes and is considered to be an igneous rock not significantly affected by metamorphism. Stannern has igneous texture but its pyroxenes indicate some re-equilibration, although little, if any, recrystallization. EET90020 has a granulite texture and has been substantially recrystallized. Our sample of Pasamonte contains several clasts of different grain sizes ranging from glass to fine grained with diabasic texture containing lathy plagioclase, unexsolved pigeonite, and mesostasis. Cores were taken of the glass and from minerals and mesostases in six lithic clasts which normally allowed sampling of more than one phase per clast. Our sample of Stannern is also a breccia but with little difference in grain size between clasts and matrix. The plagioclase and pigeonite are blocky, twinned, and exsolved and coexist with a bit of mesostasis. Cores were taken of plagioclase and pigeonite with no attempt to distinguish separate clasts. EET90020 is a granular mixture of twinned plagioclase and pigeonite having rather uniform size and many triple junctions. Several cores were taken of both phases. Both clear and cloudy grains of plagioclase and pyroxene were sampled in all three eucrites. Derived from text

WAVELENGTH DEPENDENCE OF LIMB-DARKENING OF MARS FROM VISIBLE AND NEAR-IR TELESCOPIC SPECTRAL IMAGING Abstract Only
E. Pierazzo and R. B. Singer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1139-1140 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

We are investigating the photometric properties of Mars using Earthbased telescopic spectral imaging obtained during 1988. Each spatial pixel consists of 300 spectral channels from 0.44 to 1.02 microns, calibrated to radiance factor (r(sub F)) through a careful procedure involving standard star observations in 1988 and 1990. Calibrated data include 3 spectral images with solar phase angle (g) of 12 degrees and 4 images with g of 4 degrees. Pixels near the sub-Earth point have a spatial footprint of about 280 x 150 km. Preliminary work using Hapke photometric function reveals a dependence of both single-scattering albedo and roughness parameter on wavelength. The former is in agreement with observed spectra of the martian surface, but the latter is unexpected. Derived from text

COMPOSITIONAL DIVERSITY OF THE LUNAR NORTH POLE: PRELIMINARY ANALYSES OF GALILEO SSI DATA Abstract Only
C. M. Pieters, M. Belton (Kitt Peak National Observatory, Tucson, AZ.), James W. Head, R. Greeley (Arizona State Univ., Tempe.), A. McEwen (Geological Survey, Flagstaff, AZ.), E. M. Fischer, J. M. Sunshine, K. Klaasen (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), J. Plutchak, and G. Neukum (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, Germany.) et al *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1141-1142 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

In December 1992, the Galileo spacecraft passed through the Earth-Moon system for its final gravity assist to Jupiter. The SSI camera obtained several 6-color mosaics of the lunar north polar region and the sunlit nearside and eastern limb at approximately 1.3 km/pixel. Initial analyses have concentrated on the north polar areas to assess the composition of the crust in that region. Representative 6-color calibration SSI spectra (typically 5 x 5 pixels) are shown. Photometric corrections have not yet been applied, and all spectra are scaled to unity at 0.56 microns. The data were first calibrated relative to MS2, a standard are in Mare Serenitatis (18.7 deg N, 21.5 deg E), and the top four plots of highlands, highland craters, maria, and mare craters are displayed relative to MS2. SSI spectra of areas measured with telescopic data (mare MT1/MS2 and mare crater MSA/MS2) agree well with previous data, confirming that the calibration procedures and SSI data are spectrally accurate. The bottom three plots of craters/sun have been calibrated to reflectance using previously obtained telescopic spectra of Apollo 16/MS2 (shown with Highlands/MS2) and laboratory spectra of mature Apollo 16 soil (shown for reference with the Highland Craters/Sun). Although some variations in these spectra mimic previously observed spectra of lunar terrains, several characteristics are unusual. Familiar and unfamiliar properties are observed in these northern latitudes and both types merit further investigation in their geologic context. Derived from text

OPTICAL EFFECTS OF SPACE WEATHERING ON LUNAR SOILS AND THE ROLE OF THE FINEST FRACTION Abstract Only
C. M. Pieters, E. M. Fischer, O. D. Rode (Academy of Sciences, USSR, Moscow.), and A. Basu (Indiana Univ., Bloomington.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference.

Part 3: N-Z 1993 p 1143-1144 (For primary document see N94-20636 05-91)
(Grants NAG9-184; NAGw-748)
Avail: CASI HC A01/MF A06

Lunar soils represent a cumulative product of space weathering and as such they exhibit distinct optical alteration. In comparison to the optical properties of similar rock powders, lunar soils are darker, have weaker diagnostic absorption bands, and exhibit a characteristic red continuum slope between 0.3 and 4.5 microns. Well-developed (mature) lunar soils have a mean grain size of about 60 microns and may contain more than 50 percent agglutinates (complex, glass-welded aggregates) which were previously believed to be the principal carriers of optical alteration resulting from space weathering. A detailed analysis of the spectral reflectance properties of the bulk soil, size separates, and agglutinate separates of several Apollo and Luna soils has been undertaken to evaluate the validity of the agglutinate paradigm for optical effects of space weathering. The data and results are summarized here which indicate that the finest fraction of natural lunar soils, rather than larger complex agglutinates, carries the principal effects of optical alteration. Bidirectional reflectance spectra were obtained using the small sample configuration of the RELAB facility, which accommodates 5-30 mg of material. Spectra are displayed with the labels for individual samples listed in order of brightness. Derived from text

MinMap: AN IMAGING SPECTROMETER FOR HIGH RESOLUTION COMPOSITIONAL MAPPING OF THE MOON Abstract Only **c35**
C. M. Pieters, James W. Head, and T. B. McCord (SETS Technology, Inc., Honolulu, HI.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1145-1146 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

MinMap has been selected by the Lunar Scout program to characterize and map the mineral composition of the Moon. The instrument will be built as a collaborative effort between Brown University, SETS Technology Inc., and Ball Aerospace Corp. MinMap is a visible to near-infrared imaging spectrometer that contains 192 spectral channels from 0.35-2.4 microns with signal to noise greater than 200 and 256 cross-track spatial elements. The spectrometer design has a 6 deg field of view (FOV) and utilizes grating dispersive elements and two dimensional detectors (no moving parts). An 'image cube' of data is produced that contains two dimensions of spatial information and one dimension of spectral information. All spectral channels and cross-track spatial elements are recorded simultaneously with spacecraft motion scanning the second spatial dimension. The high spectral resolution and continuous spectral range of MinMap are designed to measure the diagnostic absorption features of principal lunar minerals and their lithologic mixtures. Since the optical properties of lunar materials change in a regular manner upon exposure to the space environment, this spectral range is also quite sensitive to variations in exposure history (soil maturity). Nominal measurement stragegy is to obtain full global data of the Moon at 180 m/pixel from a 450 km polar orbit during the first month or two of operation. A 100 km orbit is anticipated for the remaining part of a 1 year mission allowing higher resolution data (approx. 80 m/pixel) to be obtained for targeted regions. MinMap exceeds LE x SWG's measurement recommendations and will provide the highest spatial resolution compositional map of lunar rocks and soils currently planned for orbital missions. Since all spectral channels are co-registered and obtained simultaneously, 'image cube' data swaths will be available for analysis almost immediately.

Almost all surfaces available for remote observation consist of particulate materials or soils. The distribution of mean particle sizes depend on the original material and physical and chemical processes that have acted on the surface over time. It is well known that the optical and infrared spectral properties of materials depends on the particle size. There has been little detailed study, however, of natural soils, namely particulate materials with a range of particle sizes. Current models for intimate mixing typically use an average particle size in calculations and are most successful when the particle size is constrained by known sieve fractions. Preliminary results of a study in which soils were prepared with a known composition and range of particle sizes are reported. This discussion presents the overall visible to infrared properties of these synthetic soils and evaluates the mid-infrared properties. Derived from text

A COMPARISON OF CALCULATED AND MEASURED RHEOLOGICAL PROPERTIES OF CRYSTALLISING LAVAS IN THE FIELD AND IN THE LABORATORY Abstract Only **c46**
Harry Pinkerton and Gill Norton *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1149-1150 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Models of most magmatic processes, including realistic models of planetary lava flows require accurate data on the rheological properties of magma. Previous studies suggest that field and laboratory rheological properties of Hawaiian lavas can be calculated from their physico-chemical properties using a non-Newtonian rheology model. The present study uses new measurements of the rheological properties of crystallizing lavas to show that this is also true for lavas from Mount Etna. Rheological measurements on quenched Etna basalts were made in a specially designed furnace using a Haake Rotovisco viscometer attached to a spindle which has been designed to eliminate slippage at the melt-spindle interface. Using this spindle, we have made measurements at lower temperatures than other workers in this field. From these measurements, Mount Etna lavas are Newtonian at temperatures above 1120 C and they are thixotropic pseudoplastic fluids with a yield strength at lower temperatures. The close agreement between calculated and measured rheology over the temperature range 1084 - 1125 C support the use of the non-Newtonian rheology model in future modeling of planetary lava flows. MAGELLAN VERTICAL POLARIZATION RADAR OBSERVATIONS Abstract Only **c32**
Jeffrey J. Plaut *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1151-1152 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The Magellan high-gain radar antenna system was designed to transmit and receive signals in a pure linear polarization state. The nominal mapping configuration placed this linear polarization direction parallel to the surface of Venus, providing SAR image data in the HH polarization (horizontal transmit and receive) and radiothermal emission data in the H (horizontal - receive only) polarization. During Magellan's extended mission (cycles 2 and 3), two brief experiments were conducted in which the spacecraft was rotated 90 degrees along the axis of the antenna boresight, producing SAR data in the VV polarization and emission data in the V polarization. This study focuses on the SAR results from the first experiment, which included portions of the highly reflective Beta Regio highlands. Theoretical models of polarimetric backscatter, along with experimental data from terrestrial surfaces, predict VV backscatter cross section values to be higher than HH values for most natural surfaces. Randomly polarized ('depolarized') backscatter from rough surfaces is expected in equal amounts for either incident polarization. Roughness differences will therefore be more pronounced in HH measurements than in VV, because the depolarized random component makes up a proportionately larger fraction of the HH backscatter. In addition, HH cross section values are observed to fall off more rapidly than VV values with increasing incidence angle. Slope-related backscatter differences will, therefore, be more pronounced in HH images. The small perturbation polarimetric scattering model also predicts higher VV to HH ratios for surfaces of high dielectric constant. Author

ERUPTION HISTORY OF THE THARSIS SHIELD VOLCANOES, MARS Abstract Only
J. B. Plescia *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1153-1154 (For

primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The Tharsis Montes volcanoes and Olympus Mons are giant shield volcanoes. Although estimates of their average surface age have been made using crater counts, the length of time required to build the shields has not been considered. Crater counts for the volcanoes indicate the constructs are young; average ages are Amazonian to Hesperian. In relative terms; Arsia Mons is the oldest, Pavonis Mons intermediate, and Ascreaus Mons the youngest of the Tharsis Montes shield; Olympus Mons is the youngest of the group. Depending upon the calibration, absolute ages range from 730 Ma to 3100 Ma for Arsia Mons and 25 Ma to 100 Ma for Olympus Mons. These absolute chronologies are highly model dependent, and indicate only the time surficial volcanism ceased, not the time over which the volcano was built. The problem of estimating the time necessary to build the volcanoes can be attacked in two ways. First, eruption rates from terrestrial and extraterrestrial examples can be used to calculate the required period of time to build the shields. Second, some relation of eruptive activity between the volcanoes can be assumed, such as they all began at a speficic time or they were active sequentially, and calculate the eruptive rate. Volumes of the shield volcanoes were derived from topographic/volume data. Derived from text

GEOLOGY OF BIBLIS PATERA, ULYSSES PATERA, AND JOVIS THOLUS, MARS Abstract Only
J. B. Plescia *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1155-1156 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

There are a variety of constructional volcanic features in Tharsis. These features range from Olympus Mons and the Tharsis Montes shields, to the small low shields and fissure eruptions that characterize much of the volcanic plains, to the smaller volcanic constructs in the northeast and western parts of Tharsis. I describe the geology of the western group, which includes Biblis Patera, Ulysses Patera, and Jovis Tholus. Each of these volcanoes has had a unique, and complex geologic history. Biblis Patera is located at 2.3 deg. N, 123.8 deg. The volcano is elongate in a northwesterly direction and has a large, faulted caldera complex. The flanks of the volcano and adjacent plains are characterized by lava flows, northwest-trending graben and troughs, and caldera-concentric graben and troughs. Biblis Patera is approximately 66 x 127 km with an oval 51 x 56 km caldera; the summit elevation is approximately 2 km above the surrounding plains. The constrcut has an estimated volume of 8-22 x 10(exp 3) cu km. Ulysses Patera is located at 2.7 deg. N, 121.3 deg. W and stands approx. 2-3 km above the surrounding plain; flank slopes are approximately 7 deg. to 12 deg. The caldera floor is quite deep, lying 1.8 to 2.2 km below the caldera rim. The caldera has a void volume of approximately 5000 cu km, the total solid mass volume of the volcano is 7-16 x 10(exp 3) cu km. Jovis Tholus is centered at 18.3 deg N; 117.5 deg W; it is a low relief, volcano with gentle flank slopes of between 3 and 8 deg. The construct is dominated by a series of inset calderas which make up the largest fraction of the area. The caldera complex is offset to the southwest side. Total shield dimensions are approximately 77 km (e-wt) by 62 km (n-s); the caldera complex is approximately 44 x 34 km. The shield is embayed on all sides by younger Amazonian age volcanics. Total relief, relative to the surrounding plains, is probably approximately 2 km. The total volume of Jovis Tholus is estimated to be approximately 2-5 x 10(exp 3) cu km. Derived from text

GRAVITY INVESTIGATION OF THE MANSON IMPACT STRUCTURE, IOWA Abstract Only **c90**
J. B. Plescia *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1157-1158 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The Manson crater, of probable Cretaceous/Tertiary age, is located in northwestern Iowa (center at 42 deg. 34.44 min N; 94 deg. 33.60 min W). A seismic reflection profile along an east west line across the crater and drill hole data indicate a crater about 35 km in diameter having the classic form for an impact crater, an uplifted central peak composed of uplifted Proterozoic crystalline bedrock, surrounded by a 'moat' filled with impact produced breccia and a ring graben zone composed of tilted fault blocks of the Proterozoic and Paleozoic country rocks. The structure has been significantly eroded. This geologic structure would be expected to produce a significant gravity signature and study of that signature would shed additional light on the details of the crater structure. A gravity study was undertaken to better resolve the crustal structure. The regional Bouguer gravity field is characterized by a southeastward decreasing field. To first order, the Bouguer gravity field can be understood in the context of the geology of the Precambrian basement. The high gravity at the southeast corner is associated with the mid-continent gravity high; the adjacent low to the northwest results from a basin containing low-density clastic sediments shed from the basement high. Modeling of a simple basin and adjacent high predicts much of the observed Bouguer gravity signature. A gravity signature due to structure associated with the Manson impact is not apparent in the Bouguer data. To resolve the gravity signature of the impact, a series of polynomial surfaces were fit to the Bouguer gravity field to isolate the small wavelength residual anomalies. The residual gravity obtained after subtracting a 5th- or 6th-order polynomial seems to remove most of the regional effects and isolate local anomalies. The pattern resolved in the residual gravity is one of a gravity high surrounded by gravity lows and in turn surrounded by isolated gravity highs. The central portion of the crater is characterized by two positive anomalies having amplitudes of about plus 4 mGal separated by a gentle saddle located approximately at the crater center. Avail: CASI HC A01/MF A06

The metal phase of ordinary chondrites has been found to contain a complex assemblage of non-metal phases, evidently formed when elements such as Si, Cr and P, originally dissolved in the metal, were subsequently oxidized and exsolved. We have investigated the Rb-Sr isotopic system in samples of H-chondrite metal, finding small but nontrivial amounts of Sr, apparently concentrated toward the surface of metal grains, and characterized by pronounced excesses of Sr-87/Sr-86 in chondritic metal can plausibly account for the characteristically elevated initial Sr-87/Sr-86 found in ordinary chondrite phosphates, but it remains unclear when and where the metal experienced the high Rb/Sr environment needed to account for such high Sr-87/Sr-86. We have previously reported Rb-Sr data for separated metal from Dhajala (H3), Forest Vale (H4) and Estacado (H6). Here we report data for two size fractions (80-160 and 280-450 microns) of separated metal from the H4 chondrite Ste. Marguerite. These samples were etched twice (.5N HCl for one hour) before dissolution (6N HCl). Aliquots of the solutions were spiked for Fe, Ca and Rb + Sr. The results for Ste. Marguerite metal are presented; errors are two-sigma and elemental concentrations are stated in terms of total sample weight.

It is apparent that few, if any, craters as old, or highly modified as Imbrian craters on the surface of the moon are present on the Venusian highlands, or indeed anywhere on the planet's surface. Degraded craters such as those seen on the Moon, Mercury, or Mars are conspicuously absent. Furthermore, virtually all the impact craters on the Venusian surface show modification only by extensional tectonics, whereas the Venusian highlands show modification by compression, strike-slip movement, and finally by extension. Presumably at an earlier time, the surface of Venus resembled the surfaces of the other inner planets. The relatively recent

resurfacing event that produced the plains units may be a mechanism for covering the older craters in the plains, but these vast outpourings of lava cannot be invoked as a mechanism for covering the craters on the Venusian highlands. If the plains units had covered the highlands, the entire Venusian surface would appear to be as smooth as the plains units that are embayed by and, therefore, postdate the highlands. The last major tectonic events to affect the highlands such as those seen on Ovda Regio appear to be thrust faulting with consequent folding, followed by at least three episodes of strike-slip faulting and finally extensional faulting. To test whether such tectonic movements could have destroyed highlands crater, a preliminary experiment was conducted by using a Lunar Orbiter mosaic of the lunar uplands as an analog for the ancient Venusian highlands.

The isotropic signatures of noble gases in the atmospheres of the Earth and other planets are considerably evolved when compared to signatures observed in the solar wind. The mechanisms driving the evolution of planetary volatiles from original compositions in the solar accretion disk are currently poorly understood. Modeling of noble-gas compositional histories requires knowledge of fractionating processes that may have operated through the evolutionary stages. Since these gases are chemically inert, information on noble-gas fractionation processes can be used as probes. The importance of understanding these processes extends well beyond 'noble-gas planetology.' Trapped argon acquired by low-energy implantation (approximately less than 100 eV) into solids is strongly mass fractionated (approximately greater than or equal to 3 percent/amu). This has potential implications for the origin and evolution of terrestrial planet atmospheres.

Avail: CASI HC A01/MF A06

Several recent studies have suggested that shock decomposition of anhydrite (CaSO4) target rocks during the K/T Chicxulub impact would have ejected tremendous amounts of sulfur gas into the stratosphere. One of the many potential biospheric effects of this sulfur gas is the generation of a sulfuric acid (H2SO4) aerosol layer capable of causing darkness and severe disruption of photosynthesis for periods of years. In this paper we report the preliminary results of our modeling of shock pressures within the anhydrites and of light attenuation by the H2SO4 aerosol cloud. These models indicate that earlier studies over-estimated the amount of sulfur gas produced, but that more than enough was produced to extend global blackout conditions 4-6 times longer than the approximately 3 month predictions for silicate dust alone.

SCHOOLS OF THE PACIFIC RAINFALL CLIMATE EXPERIMENT Abstract Only **c47**

S. E. Postawko, M. L. Morrissey, G. J. Taylor, and P. Mouginis-Mark (Hawaii Univ., Honolulu.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1167 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

The SPaRCE program is a cooperative rainfall climate field project involving high school and college level students and teachers from various Pacific island and atoll nations. The goals of the SPaRCE program are: (1) to foster interest and increase understanding among Pacific-area students and teachers of climate and climate change; (2) to educate the students and teachers as to the importance of rainfall in the Pacific area to climate studies; (3) to provide the students and teachers an opportunity of making a major contribution to the global climate research effort by collecting and analyzing Pacific rainfall data; and (4) to incorporate collected rainfall observations into a comprehensive Pacific daily rainfall data base to be used for climate research purposes. Schools participating in SPaRCE have received standard raingauges with which to measure rainfall at their sites. Students learned to site and use their raingauges by viewing a video produced at the University of Oklahoma. Four more videos will be produced which will include information on Earth's atmosphere, global climate and climate change, regional climate and implications of climate change, and how to analyze and use the rainfall data they are collecting. The videos are accompanied by workbooks which summarize the main points of each video, and contain concrete learning activities to help the student better understand climate and climate change. Following each video, interactive sessions are held with the students using the PEACESAT (Pan-Pacific Education And Communication Experiments by Satellite) satellite radio communication system.

U-Pb ISOTOPIC AGES AND CHARACTERISTICS OF ANCIENT (GREATER THAN 4.0 Ga) LUNAR HIGHLAND ROCKS Abstract Only

W. R. Premo *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1169-1170 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

A review of the present (and certainly sparse) U-Pb isotopic database for ancient (greater than 4.0 Ga) lunar highland rocks indicates that both early-forming anorthosites and high-Mg suite rocks were formed from sources with a wide variety of U-238/Pb-204(mu) values as early as 4.44 Ga. The U-Pb data from Apollo 16 anorthosites 67075, 60025, and 62337 indicate source-mu values between approximately 55 and approximately 350; whereas values for high-Mg suite rocks are tentatively considered to be over 500, similar to KREEP sources. At present, I interpret the data to indicate that either early cumulates were formed slowly in a magma environment that allowed isotopic reequilibration or mixing over a long period of crystallization, or these cumulates formed from rapidly-evolving (both geochemically and isotopically) residual liquids. It is possible that an early bombardment period played a role in the mixing process.

U-Pb PROVENANCE AGES OF SHOCKED ZIRCONS FROM THE K-T BOUNDARY, RATON BASIN, COLORADO Abstract Only **c25**

W. R. Premo and G. A. Izett *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1171-1172 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

U-Pb isotopic systematics from analyses of single zircons identify at least two provenance ages, approximately 575 Ma and approximately 330 Ma, for zircons from the impact layer of the K-T boundary, Raton Basin, Colorado. These data are a preliminary confirmation of results reported from the same layer. The zircon provenance ages provide a unique signature for identification of the source crater since igneous rocks of these ages (or sedimentary rocks derived from them) must characterize part of the impact stratigraphy.

U-Pb ISOTOPIC SYSTEMATICS OF FERROAN ANORTHOSITE 60025 Abstract Only **c25**

W. R. Premo and M. Tatsumoto *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1173-1174 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Preliminary U-Pb isotopic data from separates of ferroan anorthosite 60025 confirm its antiquity at approximately 4.42 Ga. Three Pb-Pb isochron ages involving different sets of mineral separates vary by only 20 million years, but indicate derivation of the sets from isotopically distinct magma sources. If this anorthosite was a monomict cumulate product formed during the Moon's early primary differentiation stage, then residual liquids of crystallizing magmas were evolving isotopically, even at the cm-scale, over the duration of the crystallization period. Another explanation is that this

sample is simply a polymict breccia and that the Pb isotopic results are a result of subsequent mechanical mixing of mineral assemblages from various cumulate piles formed coevally at approximately 4.42 Ga from isotopically distinct magma sources. In our ongoing search for early lunar Pb isotopic compositions, we have analyzed Apollo 16 anorthosites 67075 and 62337 and Apollo 17 high-Mg suite cumulates (troctolite 76535, norite 78235, and dunite 72415). The U-Pb isotopic systematics have been better behaved in the high-Mg suite rocks than in the anorthosites that have shown evidence of mineral assemblages of mixed parentage. Our aim in analyzing anorthosite 60025 was to avoid or minimize this problem as it had been considered essentially monomict, although recent work has shown that not only is 60025 polymict, but shows textual evidence of at least two episodes of deformation. Of five splits studied by James, Lindstrom and McGee, the four mineral splits appeared monomict, whereas the whole-rock split was considered polymict. Previous isotopic work indicate that this anorthosite was quite primitive, a claim that was apparently confirmed by the U-Pb isotopic age of 4.51 +/- .01 Ga on three plagioclase separates. However, a Sm-Nd internal isochron age of 4.44 +/- 0.02 Ga was determined using plagioclase, olivine, and mafic mineral separates, creating some doubt about the anorthosite's true age. It was pointed out that the use of slightly evolved initial Pb values (corresponding to a source-micron value of approximately 35) to correct the U-Pb data can result in an U-Pb age of 4.44 Ga. The need to resolve the age and isotopic nature of this anorthosite is paramount to furthering our understanding of processes of ferroan anorthosite formation as well as the magmatic history of the early Moon.

THERMAL CONDUCTIVITY MEASUREMENTS OF PARTICULATE MATERIALS UNDER MARTIAN CONDITIONS Abstract Only **c25**

M. A. Presley and P. R. Christensen *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1175-1176 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

The mean particle diameter of surficial units on Mars has been approximated by applying thermal inertia determinations from the Mariner 9 Infrared Radiometer and the Viking Infrared Thermal Mapper data together with thermal conductivity measurement. Several studies have used this approximation to characterize surficial units and infer their nature and possible origin. Such interpretations are possible because previous measurements of the thermal conductivity of particulate materials have shown that particle size significantly affects thermal conductivity under martian atmospheric pressures. The transfer of thermal energy due to collisions of gas molecules is the predominant mechanism of thermal conductivity in porous systems for gas pressures above about 0.01 torr. At martian atmospheric pressures the mean free path of the gas molecules becomes greater than the effective distance over which conduction takes place between the particles. Gas particles are then more likely to collide with the solid particles than they are with each other. The average heat transfer distance between particles, which is related to particle size, shape and packing, thus determines how fast heat will flow through a particulate material.The derived one-to-one correspondence of thermal inertia to mean particle diameter implies a certain homogeneity in the materials analyzed. Yet the samples used were often characterized by fairly wide ranges of particle sizes with little information about the possible distribution of sizes within those ranges. Interpretation of thermal inertia data is further limited by the lack of data on other effects on the interparticle spacing relative to particle size, such as particle shape, bimodal or polymodal mixtures of grain sizes and formation of salt cements between grains. To address these limitations and to provide a more comprehensive set of thermal conductivities vs. particle size a linear heat source apparatus, similar to that of Cremers, was assembled to provide a means of measuring the thermal conductivity of particulate samples. In order to concentrate on the dependence of the thermal conductivity on particle size, initial runs will use spherical glass beads that are precision sieved into relatively small size ranges and thoroughly washed.

ELEMENTAL DEPLETIONS IN ANTARCTIC MICROMETEORITES AND ARCTIC COSMIC SPHERULES: COMPARISON AND RELATIONSHIPS Abstract Only **c90**

T. Presper, G. Kurat, C. Koeberl (Wien Univ., Austria.), H. Palme (Max-Planck-Inst. fuer Chemie, Mainz, Germany.), and Michel Maurette (Centre de Spectrometrie Nucleaire et de Spectrometrie de Masse, Orsay, France.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1177-1178 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Antarctic micrometeorites (MM's) and Arctic cosmic spherules (CS's) have bulk compositions comparable to those of chondritic meteorites. However, abundance of Na, Ca, Mn, Ni, Co, and S are commonly lower in MM's and CS's as compared to chondrites. Our SEM, EMP, and INAA studies suggest that these elemental depletions in unmelted MM's are likely to be due to leaching of soluble components from the MM's in the upper atmosphere and the melt ice water. Depletions in CS's appear to be mainly due to volatilization during melting in the atmosphere or to sampling bias during aggregate formation or parent rock break-up.

GEOLOGIC MAPPING OF HARMAKHIS AND REULL VALLES REGION, MARS: EVIDENCE FOR MULTIPLE RESURFACING AND DRAINAGE EVENTS Abstract Only **c43**

Katherine H. Price *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1179 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Numerous mesas and irregular, channel-cut escarpments south of Harmakhis and Reull Valles suggesting at least two resurfacing events with subsequent periods of erosion are revealed from detailed geologic mapping of three adjacent 1:500,000-scale quadrangles (MTM-40262, -40267, -40272). Also, two distinct episodes of surface water runoff, each from different styles of water release, are evident. Geologic mapping is based on 1:500,000-scale photomosaics of the Harmakhis vallis region, and is an outgrowth of preliminary regional geologic mapping on a 1:2,000,000-scale on the east rim of Hellas Basin. SOME DEFORMATION TRENDS AND TOPOGRAPHIC CHARACTERISTICS OF TESSERAE ON VENUS Abstract Only

Maribeth Price and John Suppe *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1181-1182 (For primary document see N94-20636 05-91)

Avail: CASI HC A01/MF A06

Mapping of dominant trends of deformation and topographic analysis of tesserae reveal that (1) consistant patterns of deformation exist between individual tesserae; (2) regional deformation associated with coronae and rifts commonly overprints tesserae fabrics; (3) normalized area frequency plots of tesserae display a strongly bimodal distribution between -70 to 70 degrees latitude; and (4) the relief at tessera margins is relatively constant and independent of tessera elevation. We are continuing to expand these observations and test their implications for the formation of tesserae and for global models of deformation on Venus.

OXYGEN ISOTOPIC RELATIONSHIPS BETWEEN THE LEW85332 CARBONACEOUS CHONDRITE AND CR CHONDRITES Abstract Only **c90**
M. Prinz, M. K. Weisberg, R. N. Clayton (Chicago Univ., IL.), and T. K. Mayeda (Chicago Univ., IL.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1185-1186 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

LEW85332, originally described as a unique C3 chondrite, was shown to be a C2 chondrite with important linkages to the CR clan. An important petrologic aspect of LEW85332 is that it contains anhydrous chondrules and hydrated matrix, and new oxygen isotopic data on chondrules, matrix and whole rock are consistent with the petrology. Chondrules fall on the equilibrated chondrite line (ECL), with a slope near 1, which goes through ordinary chondrite chondrules. This contrasts with the CR chondrule line which has a lower slope due to hydrated components. LEW85332 chondrules define a new carbonaceous chondrite chondrule line, parallel to the anhydrous CV chondrule line (CCC), consistent with the well-established concept of two oxygen isotopic reservoirs. Matrix and whole rock fall on the CR line. The whole rock composition indicates that the chondrite is dominated by chondrules, and that most of them contain light oxygen similar to that of anhydrous olivine and pyroxene separates in the Renazzo and Al Rais CR chondrites. CHOCOLATE TABLET ASPECTS OF CYTHEREAN MESHKENET TESSERA Abstract Only
J. Raitala *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1189-1190 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Meshkenet Tessera structures were mapped from Magellan data and several resemblances to chocolate tablet boudinage were found. The complex fault sets display polyphase tectonic sequences of a few main deformation phases. Shear and tension have contributed to the areal deformation. Main faults cut the 1600-km long Meshkenet Tessera highland into bar-like blocks which have ridge and groove pattern oriented along or at high angles to the faults. The first approach to the surface block deformation is an assumption of initial parallel shear faulting followed by a chocolate tablet boudinage. Major faults which cut Meshkenet Tessera into rectangular blocks have been active repetitively while two progressive or superposed boudinage set formations have taken place at high angles during the relaxational or flattening type deformation of the area. Chocolate tablet boudinage is caused by a layer-parallel two-dimensional extension resulting in fracturing of the competent layer. Such structures, defined by two sets of boudin neck lines at right angles to each other, have been described by a number of authors. They develop in a flattening type of bulk deformation or during superposed deformation where the rock is elongated in two dimensions parallel to the surface. This is an attempt to describe and understand the formation and development of structures of Meshkenet Tessera which has complicated fault structures. Derived from text

RIDGE BELT-RELATED SCARPS AND TROUGHS: COMPRESSIONAL CRUSTAL BENDING ON VENUS Abstract Only
J. Raitala, T. Toermaenen, K. Kauhanen, and T. Tokkonen *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1191-1192 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Cytherean ridge arcs resulted in crustal shortening in places with either the strongest compression or weakest surface layers. Arcuate scarps on or close to the edge of the ridge arcs were compressional fronts formed by overthrust over or subduction of adjacent lowland. These ridge arcs became wider due to the propagation of new ridge formation close to previous one(s). As this process repeated itself with time, the crust became thicker and the foreland was bent either due to the excess load, overthrust or subduction event. The Salme Dorsa arc measures 100 km in width and 600 km in length. It consists of a horseshoe-like set of ridges and grooves on a gently sloping lowland. The westward arcuate ridge belt indicates lateral compressional stresses and crustal deformation from SE against the southern Ishtar Terra foreland plain. The trough on the western side of the ridge belt and tensional grabens close to the crest of the bulge to the west of the trough are due to the crustal bending and indicate effects of the load and thrust. Compression and relative movement from southeast against and over the foreland planitia have resulted in ridge belt, trough and bulge formation. The load- and/or stress-induced bending of the uppermost crust allows some estimations of the uppermost elastic lithosphere thickness. Repeated folding and thrust faulting of surface layers due to compression are indicated by four more ridge belts located close to Salme Dorsa. The northeasternmost one has short ridges located in troughs. The west-opening arcuate ridge belt interlocks with the Salme Dorsa horseshoe. Derived from text

KALKKOP CRATER, EASTERN CAPE: A NEW IMPACT CRATER IN SOUTH AFRICA Abstract Only **c46**
W. U. Reimold, F. G. LeRoux (Geological Survey of South-West Africa/Namibia, Windhoek.), C. Koeberl (Wien Univ., Austria.), and S. B.

Shirey (Wien Univ., Austria.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1197-1198 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Reimold et al. suggested that the 640 m diameter Kalkkop crater, at 32 deg 43 min S/24 deg 34 min E in the Eastern Cape Province (South Africa), could possibly be of impact origin. This idea was based on the circularity of this structure, its regional uniqueness, lack of recent igneous activity in the region, and descriptions of drillcore indicating that the crater is not underlain by a salt dome and is partially filled with a breccia layer of a thickness which would agree with the dimensions expected for an impact structure of this size. Unfortunately the old drillcore was no longer available for detailed study, and in the absence of sufficient surface exposure only drilling could provide the evidence needed to solve the problem of the origin of Kalkkop. For this reason and to study the crater fill from a paleoenvironmental point of view, the S. African Geological Survey decided to sponsor a new research drilling project at the Kalkkop site. First petrographic and isotopic results from Kalkkop drill core studies confirming, without doubt, that this crater is of impact origin are presented.

MICROMETEORITE DYNAMIC PYROMETAMORPHISM: NONSTOICHIOMETRIC CLINOENSTATITE (CLEN) Abstract Only **c90**
Frans J. M. Rietmeijer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1199-1200 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Polymorphs of enstatite are common phases in many meteorites. They contain clues on their formation and the thermal evolution of their host rock which includes shock metamorphism. Rare, micron-sized, CLEN whickers and thin platelets in chondritic porous micrometeorites were interpreted as solar nebula condensates that remained unaffected during atmospheric entry flash-heating. This CLEN formed by protoenstatite (PEN) inversion whereby the surface energy of the micron-sized PEN crystals aided the OREN-CLEN transformation or by metastable growth. Ca-poor, Mg,Fe-pyroxene with unequilibrated, intraparticle, Mg/(Mg+Fe) distributions occur in most chondritic micrometeorites. These distributions are a parent body signature that survived dynamic pyrometamorphism because the duration of the thermal spike during atmospheric entry is too short but this conclusion does not consider the ultrafine grain size of micrometeorites. The maximum temperature and duration of the heating event will depend on the kinetic energy and entry angle of the incoming micrometeorite. But lacking detailed petrological data for an individual particle, its thermal profile during atmospheric entry can not be deduced from its mass alone as a function of entry angle. In order to constrain dynamic pyrometamorphism in unmelted micrometeorites, I determined the petrological composition and silicate mineralogy in non-chondritic micrometeorites L2005T13, L2005E40, and L2006A28. Author (revised)

MICROMETEORITE DYNAMIC PYROMETAMORPHISM: OBSERVATION OF A THERMAL GRADIENT IN IRON-NICKEL SULFIDE Abstract Only **c90**
Frans J. M. Rietmeijer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1201-1202 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Dynamic pyrometamorphism describes the mineralogical changes in a micrometeorite that occur in response to flash-heating during atmospheric entry. Mineral reactions during this event will be endothermic and act as local sinks for thermal energy which delays a uniform temperature distribution in decelerating micrometeorites. The most common pyrometamorphic reaction is formation of magnetite nanocrystal decorations on Mg,Fe-silicate grains and magnetite or (partial) maghemite rims. Constituent silicates also respond to this thermal event and show formation of olivine-maghemite symplectites and growth of garnet and partial laihunitisation. In continued effort to constrain dynamic pyrometamorphism of unmelted interplanetary dust particles (IDP's), I determined the mineralogical composition, and Fe,Ni-sulfide chemistry, in the sulfide-rich particles L2005C39, L2005E40, and L2006A28 using a JEOL 2000FX analytical electron microscope equipped with a TN5500 energy dispersive spectrometer for in situ microanalysis. Sulfide compositions in these three IDP's are distinctly different from those in silicate-rich particle L2005T13 which might suggest a delicate balance of the fO2/fS2 ratios during dynamic pyrometamorphism.

PRELIMINARY RESULTS FROM MARINER 10: HIGH RESOLUTION IMAGES OF THE MOON Abstract Only
Mark S. Robinson, B. Ray Hawke, Kay Edwards (Geological Survey, Flagstaff, AZ.), Paul G. Lucey, and Beth E. Clark *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1207-1208 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

In November of 1973 the Mariner 10 spacecraft acquired high resolution images of both the Earth and the Moon as it began its voyage to Venus and then Mercury. The best images had a resolution of approximately 1 km and were taken from an unusual viewpoint, above the lunar North Pole. At this time the Moon was illuminated such that the eastern limb, including approximately 30 degrees of the farside, was visible. Two high resolution mosaics were acquired during this period which provide excellent views of regions of the Moon poorly seen from the Earth. These include the Frigoris, Humboldtianum, Marginis, and Smythii regions. These images also covered expanses of highlands not visible from the Earth. These data were unique in that they were the only useful robotic spacecraft images of the Moon; and they remained so until December of 1990 when the Galileo spacecraft made its first encounter with the Moon. These Mariner 10 lunar images were acquired and are currently being used in conjunction with Earth-based telescopic spectra as well as Apollo and Lunar Orbiter photographic data to investigate the nature of deposits comprising the Northeast Nearside of the Moon. These Mariner 10 frames have proved useful for photogeologic, photometric, and photoclinometric analyses; they were also used in support of the second Galileo lunar encounter of December 1992.

CHRONOLOGY, ERUPTION DURATION, AND ATMOSPHERIC CONTRIBUTION OF APOLLINARIS PATERA, MARS Abstract Only
M. S. Robinson, P. J. Mouginis-Mark, J. R. Zimbelman (Smithsonian Institution, Washington, DC.), and S. S. C. Wu (Geological Survey, Flagstaff, AZ.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1209-1210 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Geologic mapping from Viking image data of the Martian volcano Apollinaris Patera allowed identification of 6 major events that shaped its current morphology. Derivation of new topographic data allowed accurate estimates of the volume of erupted products from which estimates of an eruption duration are presented for the edifice and its corresponding atmospheric water contribution. Topographic data were acquired using stereophotogrammetric (Viking picnos 603A42, 639A92) techniques in both profiling and contouring modes (1 km contour). The profiling mode results in a more precise measurement than the contouring mode, but is limited in its areal coverage. The contour data are used in a more general sense to provide synoptic coverage for the volcano. These new stereophotogrammetric measurements constrain the topography to an accuracy of approximately 800 m vertically and approximately 1000 m horizontally. Conversion of the derived contour map to a raster based digital elevation model (DEM) was done by a growing contours interpolation. An ambiguity arises in this volume calculation due to an uncertainty regarding the actual base of the volcano relative to the pre-existing topography. Thus, the volume estimate was bracketed by using the 100 m and the 750 m elevations, which generally correspond to the lower and upper portions of the circumferential basal scarp, respectively. The resulting volumes are 103,000 cu km and 97,000 cu km; therefore the total volume of Apollinaris Patera is estimated to be approximately 100,000 cu km.

THE MANSON IMPACT CRATER: ESTIMATION OF THE ENERGY OF FORMATION, POSSIBLE SIZE OF THE IMPACTING ASTEROID OR COMET, AND EJECTA VOLUME AND MASS Abstract Only **c90**
D. J. Roddy, E. M. Shoemaker, and R. R. Anderson (Geological Survey, Iowa City, IA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1211-1212 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A research program on the Manson impact structure has substantially improved our knowledge of the detailed features of this eroded crater. As part of our structural studies, we have derived a value of 21 km for the diameter of the final transient cavity formed during crater excavation. With this information, we can estimate the energy of formation of the Manson crater and the possible size of the impacting asteroid or comet. In addition, we have estimated the near- and far-field ejecta volumes and masses.

COMPARATIVE HYPSOMETRIC ANALYSIS OF BOTH EARTH AND VENUS TOPOGRAPHIC DISTRIBUTIONS Abstract Only
P. Rosenblatt, P. C. Pinet, and E. Thouvenot *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1213-1214 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Previous studies have compared the global topographic distribution of both planets by means of differential hypsometric curves. For the purpose of comparison, the terrestrial oceanic load was removed, and a reference base level was acquired. It was chosen on the basis of geometric considerations and reflected the geometric shape of the mean dynamical equilibrium figure of the planetary surface in both cases. This reference level corresponds to the well-known sea level for the Earth; for Venus, given its slow rate of rotation, a sphere of radius close to the mean, median and modal values of the planetary radii distribution were considered and the radius value of 6051 km arbitrarily taken. These studies were based on the low resolution (100 x 100 sq km) coverage of Venus obtained by the Pioneer Venus altimeter and on the 1 deg x 1 deg terrestrial topography. But, apart from revealing the distinct contrast existing between the Earth's bimodal and Venus' strong unimodal topographic distribution, the choice of such a reference level is inadequate and even misleading for the comparative geophysical understanding of the planetary relief distribution. The present work reinvestigates the comparison between Earth and Venus hypsometric distribution on the basis of the high-resolution data provided, on one hand, by the recent Magellan global topographic coverage of Venus' surface, and on the other hand, by the detailed NCAR 5 x 5 ft. grid topographic database currently available for the Earth's surface.

There is ample theoretical and observational evidence suggesting liquid water was once stable at the surface of Mars. Because water is essential to the evolution of life, it is important to understand the types of environments in which the liquid water was present. For example, if water were present early in Mars' history, then this raises the possibility that biological activity may have evolved only to eventually become extinct as liquid water became scarce. Alternatively, if liquid water were stable only later in Mars' history, then it becomes problematic to envision mechanisms by which biological activity evolved and remained viable without water until more favorable conditions existed. Even without biological activity, atmospheric carbon dioxide dissolved in water can assist the chemical weathering of primary igneous minerals producing common secondary phases such as hydartes, carbonates, and sulfates. While the identification of hydrates, carbonates, and sulfates on Mars cannot provide direct evidence of biological activity, it can provide significant information regarding the presence and duration of an environment that would support the presence of liquid water at the surface. The specific mineralogy of these secondary phases can provide insight into the environments of their formation. For example, the slow precipitation that occurs in large standing bodies of water, e.g. oceans or lakes, commonly results in the formation of calcite, magnesite, dolomite, siderite, and rhodochrosite. Rapid precipitation that occurs in ephemeral bodies of water, e.g. hypersaline lakes or playas, can result in the formation of all of the above phases as well as aragonite, vaterite, hydrated carbonates, alkali carbonates, bicarbonates, and other poorly ordered phases. Absorption features identified in recent near-infrared spectra of Mars have been interpreted as being due to bicarbonate and bisulfate located in the mineral scaplite. Spectral data returned by the Mariner 6 and 7 spacecraft have been inerpreted as remaining consistent with the presence of hydrated carbonates. Additional, airborne thermal infrared spectra of Mars have been interpreted as implying the presence of carbonates, sulfates, and hydrates. Modeling of the thermal infrared data relied upon the optical constants of calcite anhydrite and a mixture of water in basalt because of their availability. The derived abundances of carbonate and sulfate were 1-3 percent and 10-15 percent by volume. However, the observed complexity and positions of the bands suggested other carbonate-, and sulfate-bearing species. We have already derived optical constants for hydrous and anhydrous silicates, and we are now applying these techniques to the derivation of the optical constants of hydrous carbonate and sulfate. EUHEDRAL METALLIC-Fe-Ni GRAINS IN EXTRATERRESTRIAL SAMPLES Abstract Only **c26**
Alan E. Rubin *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1217-1218 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Metallic Fe-Ni is rare in terrestrial rocks, being largely restricted to serpentinized peridotites and volcanic rocks that assimilated carbonaceous material. In contrast, metallic Fe-Ni is nearly ubiquitous among extraterrestrial samples (i.e., meteorites, lunar rocks, and interplanetary dust particles). Anhedral grains are common. For example, in eucrites and lunar basalts,

most of the metallic Fe-Ni occurs interstitially between silicate grains and thus tends to have irregular morphologies. In many porphyritic chondrules, metallic Fe-Ni and troilite form rounded blebs in the mesostasis because their precursors were immiscible droplets. In metamorphosed ordinary chondrites, metallic Fe-Ni and troilite form coarse anhedral grains. Some of the metallic Fe-Ni and troilite grains has also been mobilized and injected into fractures in adjacent silicate grains where local shock-reheating temperatures reached the Fe-FeS eutectic (988 C). In interplanetary dust particles metallic Fe-Ni most commonly occurs along with sulfide as spheroids and fragments. Euhedral metallic Fe-Ni grains are extremely rare. Several conditions must be met before such grains can form: (1) grain growth must occur at free surfaces, restricting euhedral metallic Fe-Ni grains to systems that are igneous or undergoing vapor-deposition; (2) the metal (+/-) sulfide assemblage must have an appropriate bulk composition so that taenite is the liquidus phase in igneous systems or the stable condensate phase in vapor-deposition systems; and (3) metallic Fe-Ni grains must remain underformed during subsequent compaction, thermal metamorphism, and shock. Because of these restrictions, the occurrence of euhedral metallic Fe-Ni grains in an object can potentially provide important petrogenetic information. Despite its rarity, euhedral metallic Fe-Ni occurs in a wide variety of extraterrestrial materials. Some of these materials formed in the solar nebula; others formed on parent body surfaces by meteoroid impacts. Author (revised)

NAMED VENUSIAN CRATERS Abstract Only
Joel F. Russell and Gerald G. Schaber *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1219-1220 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Schaber et al. compiled a database of 841 craters on Venus, based on Magellan coverage of 89 percent of the planet's surface. That database, derived from coverage of approximately 98 percent of Venus' surface, has been expanded to 912 craters, ranging in diameter from 1.5 to 280 km. About 150 of the larger craters were previously identified by Pioneer Venus and Soviet Venera projects and subsequently formally named by the International Astronomical Union (IAU). Altogether, the crater names submitted to the IAU for approval to date number about 550, a little more than half of the number of craters identified on Magellan images. The IAU will consider more names as they are submitted for approval. Anyone--planetary scientist or layman--may submit names; however, candidate names must conform to IAU rules. The person to be honored must be deceased for at least three years, must not be a religious figure or a military or political figure of the 19th or 20th century, and, for Venus, must be a woman. All formally and provisionally approved names for Venusian impact craters, along with their latitude, longitude, size, and origin of their name, will be presented at LPSC and will be available as handouts. A CARBON AND NITROGEN ISOTOPE STUDY OF CARBONACEOUS VEIN MATERIAL IN UREILITE METEORITES Abstract Only **c90**
S. S. Russell, J. W. Arden, I. A. Franchi, and C. T. Pillinger *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1221-1222 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The ureilite meteorite group is known to be rich in carbon in the form of graphite/diamond veins that are associated with planetary type noble gases. This paper reports preliminary data from a systematic study of the carbon and nitrogen isotopic composition of this carbonaceous vein material. A previous study focused on the whole rock signatures and reported that the carbon inventory appeared to be dominated by the graphitic/diamond intergrowths, whereas the nitrogen was clearly composed of several distinct components including one that was isotopically light, possibly associated with the carbonaceous material. Recent studies have demonstrated that diamonds in the solar system formed in many different environments. C and N measurements from ureilitic diamond made in a similar way would be a useful addition to this overall study. The methods used for isolating diamonds of possible presolar origin from primitive meteorites are equally applicable to the processing of carbon bearing components in the ureilite group so that their stable isotopic composition can be determined. Herein we discuss conjoint C and N stepped combustion measurements made on crushed whole rock ureilite samples that have been treated with 1M HCl/9M HF to dissolve silicate and free metal. In addition, two samples have been further treated with oxidizing acids to leave a diamond rich residue. Author (revised)

C-O VOLATILES IN APOLLO 15 AND APOLLO 17 PICRITIC GLASSES Abstract Only **c25**
Malcolm J. Rutherford and Robert A. Fogel (American Museum of Natural History, New York, NY.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1223-1224 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A15 and A17 primitive picritic glasses have been examined by FTIR for the presence of dissolved C-O species to determine the role of C-O gasses on driving lunar fire-fountains. A15 green and yellow glasses were extensively studied and found to be free of dissolved C species down to FTIR detection limits (10-100 ppm; species and sample specific). Preliminary data on A17 orange glasses are similarly devoid of FTIR detectable C-O species. Re-analyses of the C-O driving mechanism theory for mare volcanism demonstrates the need to determine the fO2 of the lunar interior; the factor that most critically determined the role of C gasses in the fire-fountaining events. Oxygen fugacities equivalent to IW-0.5 and above imply dissolved CO3(=) in the primitive glasses at levels above FTIR detection. The f02's below IW-0.5 imply concentrations of CO3(=) below FTIR detection. Recent data suggesting lunar mantle fO2's of IW-2 or less, strongly mitigate against finding FTIR measurable dissolved CO3(=) consistent with the findings of this study. Author (revised)

FORMATION OF THE LOW-MASS SOLAR NEBULA **c92**
T. V. Ruzmaikina, I. V. Khatuncev (Academy of Sciences, USSR, Moscow.), and T. V. Konkina (Academy of Sciences, USSR, Moscow.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1225-1226 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

We study an accretional stage of the formation and early evolution of the solar nebula with relatively small angular momentum. We investigate the evolution of the disk and its vertical structure, particularly the shock front between disk and infalling material. Calculations start at a moment when a low-mass star-like core surrounded by small embryo disk have been formed at the center of the presolar nebula and the bulk of mass remained in the envelope. The forming solar nebula is approximated as a thin viscous disk surrounded by accreting envelope. The distribution of temperature in the infalling envelope is determined by solving spherically symmetric equations of radiative transfer. As the energy source, we take into account all energy released within the centrifugal radius of the infalling matter. Other aspects of this study are discussed. Derived from text

ASTEROID COLLISIONS: TARGET SIZE EFFECTS AND RESULTANT VELOCITY DISTRIBUTIONS Abstract Only **c90**
Eileen V. Ryan *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1227-1228 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

To study the dynamic fragmentation of rock to simulate asteroid collisions, we use a 2-D, continuum damage numerical hydrocode which models two-body impacts. This hydrocode monitors stress wave propagation and interaction within the target body, and includes a physical model for the formation and growth of cracks in rock. With this algorithm we have successfully reproduced fragment size distributions and mean ejecta speeds from laboratory impact experiments using basalt, and weak and strong mortar as target materials. Using the hydrocode, we have determined that the energy needed to fracture a body has a much stronger dependence on target size than predicted from most scaling theories. In addition, velocity distributions obtained indicate that mean ejecta speeds resulting from large-body collisions do not exceed escape velocities. Derived from text

DETECTABILITY OF CRYSTALLINE FERRIC AND FERROUS MINERALS ON MARS Abstract Only
Donald E. Sabol, Jr., James F. Bell, III (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.), and John B. Adams *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1229-1230 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Telescopic and spacecraft spectroscopic and geochemical data have been used to constrain the surface mineralogy of Mars and to yield clues about past and present Mars surface weathering/alteration scenarios. Based primarily on their visible to near-IR reflectance properties, several terrestrial iron-bearing minerals have been either identified on Mars or proposed as Mars spectral analogs. Among these are crystalline hematite, pyroxenes, as well as poorly crystalline materials like nonophase hematite and palagonite. Other iron-bearing minerals include nontronite, magnetite, jarosite, and goethite and the have been proposed as Mars surface constituents based on Viking Lander measurements or geochemical modeling. If present on Mars, these materials likely appear as spectral mixtures at the coarse spatial resolution of remotely sensed data. The detectability of any of these components must be evaluated relative to the other components with which they occur. The primary goal of this study is to determine how much of any given mineral would have to be present for it to be detectable in remotely-sensed data. Here, the detectability of iron-bearing minerals was evaluated using detection threshold analysis (DTA), an analytical technique based on spectral mixture analysis. Derived from text

DISTRIBUTION OF SMALL VOLCANIC CONES ON THE SURFACE OF VENUS BY SIZE AND ELEVATION: IMPLICATIONS FOR DIFFERENTIAL DEPOSITION OF VOLCANIC FEATURES Abstract Only
J. F. Lockwood, Mike Ellison, J. Johnson (Arizona Univ., Tucson.), and G. Kamatsu (Arizona Univ., Tucson.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1231-1232 Prepared in cooperation with Evergreen High School, Vancouver, WA (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

It appears that volcanic features are not evenly distributed on the surface of Venus. Head et. al. theorizes that the sparcity of volcanic features in the lowlands may be due to an altitude dependent inhibition of volatile exsolution and the resulting products of neutral buoyancy zones sufficient to form magma reservoirs and favoring flood lavas at lower elevation. The astronomy research classes of Evergreen and Sahuaro High Schools surveyed a cross-section of different elevation topography to investigate size and distribution of small volcanic cones by elevation. The results from this survey are presented. Derived from text

VENUS PANCAKE DOME FORMATION: MORPHOLOGIC EFFECTS OF A COOLING-INDUCED VARIABLE VISCOSITY DURING EMPLACEMENT Abstract Only
S. E. H. Sakimoto and M. T. Zuber *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1233-1234 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The distinctive steep-sided 'pancake' domes discovered in the Magellan images of Venus have morphologies that suggest formation by a single continuous emplacement of a high viscosity magma. A resemblance of the venusian domes to much smaller terrestrial rhyolite and dacite volcanic domes has prompted some authors to suggest that the domes on Venus also have high silica compositions and thus, high viscosities. However, viscosity is a function of crystallinity as well as silica content in a magma, and thus increases as a result of magmatic cooling. To investigate the effect of a cooling-induced viscosity increase on dome morphology, we have modeled the domes as radial viscous gravity currents that cool during emplacement. Various aspects of the investigation are discussed.

THERMAL INFRARED REMOTE SENSING AND KIRCHHOFF'S LAW: 1. LABORATORY MEASUREMENTS Abstract Only **c25**
J. W. Salisbury, A. Wald, and D. M. DAria *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1235-1236 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Kirchoff's Law, as originally conceived, applies only to samples in thermal equilibrium with their surroundings. Most laboratory measurements of emissivity only approach this condition and it never applies in remote sensing applications. In particular, the background is often much cooler than the radiating sample, and this has led to a long controversy about the applicability of Kirchhoff's Law under such conditions. It has also led to field and laboratory measurement techniques that use some form of the 'emissivity box' approach, which surrounds the sample with a background as close as possible to the sample temperature. In our experiments, we have heated soil samples in air on a hot plate in the laboratory to a much higher temperature than the room temperature background. Spectral emissivity was measured, except the known emissivities of both the primary and secondary Christiansen features were used, instead of assuming an emissivity of unity at these wavelengths. The results from this investigation are discussed in brief. Derived from text

VENUS' IMPACT-CRATER DATABASE: UPDATE TO APPROXIMATELY 98 PERCENT OF THE PLANET'S SURFACE Abstract Only
Gerald G. Schaber and David J. Chadwick *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1241-1242 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A total of 912 impact craters between 1.5 and 280 km in diameter have now been identified on about 98% of Venus' surface. This total includes an additional 71 craters (mostly in the southern hemisphere) not in the crater inventory given in Schaber et al. for 89% of the planet. (Extrapolated to 100% of the surface, the inventory should consist of 930 craters greater than 1.5 km in diameter.) The total crater inventory for 98% of the planet is only slightly larger (912 versus 882) than that extrapolated from the inventory of 135 craters when only 15% of the planet had been mapped by Magellan. The remarkably consistent density of about 2.02 impact craters per 10(exp 6) sq km emphasizes the completely random nature of the crater population's distribution. About 400 craters recognized from Magellan mapping have been assigned names.

LOCAL TOPOGRAPHY OF MARS AND ITS RELATIONSHIP TO SURFACE WEATHERING PROCESSES Abstract Only
M. W. Schaefer *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1243-1244 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

There is a growing body of evidence in favor of the importance of aqueous sedimentary processes on Mars. It is important to understand the role that surface weathering processes have played in the development of the present morphology of the Martian surface. Such an understanding is important not only for its relevance to the study of volatile sources and sinks on Mars through time, but also for its relevance to Martian geologic and tectonic history. Starting in the fall of this year, the Mars Observer Laser Altimeter will begin sending back to Earth data on the topography of Mars that is of a higher quality than most of the topography data available for the Earth. This data will be invaluable, not only for understanding global and large-scale regional processes and landforms on Mars, but also for the study of local and smaller-scale regional processes and landforms. Digital topography is an important part of geologic and geomorphic studies, useful in distinguishing between different lithologies and between different types of weathering. Digital topography data may be used to study a wide variety of local and regional-scale landforms, including valleys, sand dunes, lava flows, landslides, and slopes. Topography data are also essential to the analysis of spectral response patterns, especially in areas of high topographic relief. Geomorphic classification can be significantly improved by the addition of topographic information. Derived from text

GEOLOGY OF THE SOUTHERN HEMISPHERE OF TRITON: NO POLAR CAP Abstract Only
P. Schenk and J. M. Moore (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) *In its* Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1247-1248 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The bright southern hemisphere, comprising Uhlanga Regio, is perhaps the most poorly understood geologic province on Triton. The entire bright southern hemisphere has been described as a bright polar 'cap', implying a seasonal origin, or as a permanent geologic terrain distinct from the equatorial terrains. Also, thermal models have predicted seasonal migration of frosts and ices from the presently sun-lit south latitudes to the dark northern latitudes. The distribution of frosts and geologic history of this region must be determined observationally. We reexamine the geology of this terrain with the goal of answering these questions. Derived from text

THE 3-D MOONS: THE VOYAGER STEREO ATLAS OF THE OUTER SOLAR SYSTEM Abstract Only
P. Schenk and J. M. Moore (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) *In its* Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1249-1250 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Comprehension and analysis of geologic features on any planet is enhanced manyfold by a clear perception between albedo and topography. On many of the icy satellites significant albedo contrasts due to mixtures of dark rocky and bright icy materials can be associated with topographic features. Subtle topographic features can be masked by albedo variation and under high solar illumination albedo and topography can be difficult to separate. To this end we are compiling an atlas of stereo image pairs of the outer solar system based on Voyager imaging for the investigation of various geologic problems and for general use. For the icy satellites, general perceptions of topography are usually gleaned from shape-from-shading information in the images processed by the human brain (i.e. visual inspection). With few exceptions, actual topography has been measured on a spot-by-spot basis using shadow heights or photoclinometry, or along limb profiles (where geographic context may be unavailable). Shadow heights are limited to regions within approximately 10 deg of the terminator and images with resolution better than approximately 1 km/pixel. Photoclinometric scans can be used more widely but are subject to a variety of errors, primarily uncertain assumptions of uniform scene albedo or poorly understood photometry. Stereoscopic analysis, where available, has the potential for greatly expanding topographic perception. Derived from text

Avail: CASI HC A01/MF A06

Excess Ir found in sediments at the Cretaceous/Tertiary (K/T) boundary and in other (e.g., Pliocene) sediments from deep sea drilling cores is widely interpreted as evidence of major impact events. The Australasian tektites originated in an impact event approximately 0.77 Ma ago; microtektites have been found in deep-sea sediment cores throughout the Indian Ocean, the Philippine Sea, and western Pacific Ocean, but Ir has not been previously reported in these horizons. The deep-sea record of tektites is of particular interest, because in contrast to most continental occurrences, the stratigraphy preserves the original depositional position. Recently several cores having exceptionally high contents of Australasian microtektites have been investigated, Glass and Wu found shocked quartz associated with the microtektites. We used neutron activation to determine concentrations of Ir and other elements in two cores bearing microtektites, one from Deep Sea Drilling Project (DSDP) hole 758B in the Eastern Indian Ocean and one from DSDP hole 769A in the Sulu Sea (near Mindanao, Philippines). The sedimentation age for the microtektite layers in core 758B lies between 0.73 - 0.78 Ma and agrees well with the mean laser-fusion Ar-40/Ar-39 age of Australasian tektites of 0.77 +/- 0.02 Ma by Izett et al. We are able to resolve a small positive Ir enhancement in 758B. Core 769A shows too much scatter to allow resolution of an Ir peak. Derived from text

PRESSURE VERSUS DRAG EFFECTS ON CRATER SIZE Abstract Only **c46**
R. M. Schmidt *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1253-1254 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The topic of atmospheric effects on crater formation is very complex because it includes not only pressure effects on excavation, but also drag effects on ejecta placement. Experiments have to be designed very carefully to allow isolation of the two phenomena. Historically, numerous investigators have shown an influence of atmospheric pressure. However, none have identified the scaling that correctly isolates pressure from drag effects. On-going work in explosive cratering has produced scaling paradigms for deeply buried explosive charges where drag effects are negligible. Here it was found that increased pressure caused significant induced strength effects that impeded crater excavation. The effect is more pronounced with increasing burial depth and less pronounced with increased yield.

SEARCHING FOR ANCIENT VENUS Abstract Only

Peter H. Schultz *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1255-1256 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The cratering record on Venus provides one of the few available remote chronometers for establishing relative age. Because the dense atmosphere shields the surface from smaller impactors, the most statistically significant fraction of the cratering record is incomplete at best and indeterminate at worst. Larger craters represent survivors of entry but occur too infrequently for delineating statistically significant ages on a local scale. This contribution reconsiders processes affecting the statistical cratering record and argues that the globally averaged age approaches 2-3 billion years with isolated relict surfaces dating back to 3-4 billion years. The relation between the depth and diameter of excavation for impacts typically is assumed to be proportional. Such an assumption is consistent with the constant aspect ratio (diameter:depth) observed for simple craters found in a wide range of planetary settings and crater-scaling laws derived from laboratory experiments. Although complex craters exhibit evidence for floor uplift and rim collapse of a transient profile, they are typically thought to resemble initially smaller, simple craters. At large scales, however, early-time processes consume a greater fraction of crater growth and the assumption of late-time equivalence of energy release as a point source becomes inappropriate. The authors propose instead that crater diameter, depth, and impactor penetration represent separable dependent variables that underscore the fundamental difference between impact and point-source explosion excavation processes. An important consequence of this perspective is that central pits, peaks, and rings may represent contrasting target responses to impactor penetration and could provide an important indicator of impactor dimensions. FURTHER ANALYSES OF RIO CUARTO IMPACT GLASS Abstract Only **c25**
Peter H. Schultz, T. E. Bunch (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.), C. Koeberl (Wien Univ., Austria.), and W. Collins *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1259-1260 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Initial analyses of the geologic setting, petrology, and geochemistry of glasses recovered from within and around the elongate Rio Cuarto (RC) craters in Argentina focused on selected samples in order to document the general similarity with impactites around other terrestrial impact craters and to establish their origin. Continued analysis has surveyed the diversity in compositions for a range of samples, examined further evidence for temperature and pressure history, and compared the results with experimentally fused loess from oblique hypervelocity impacts. These new results not only firmly establish their impact origin but provide new insight on the impact process. Author

C2, CN AND DUST IN COMET WILSON (1987VII) Abstract Only **c90**
R. Schulz, M. F. AHearn, P. V. Birch (Perth Observatory, Australia.), C. Bowers (Perth Observatory, Australia.), M. Kempin (Perth Observatory, Australia.), and R. Martin (Perth Observatory, Australia.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1261-1262 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Column density profiles in C2 and CN as well as in blue and red continuum (BC and RC) were constructed from two dimensional images of the coma of Comet Wilson (1987VII). The authors' analysis showed that the continuum profiles decrease with the nuclear distance rho as 1/rho. From the C2 and CN profiles the authors determined the parent and the daughter lifetimes as well as the production rates in terms of the vectorial model. Author (revised)

Basaltic rocks are thought to constitute a volumetrically significant rock type on the Moon, Mercury, Mars, and Venus, in addition to the Earth. Spacecraft images of surfaces with known or suspected basaltic composition on these bodies, particularly on Venus, indicate that these rocks have been deformed in the brittle regime to form faults and perhaps dilatant cracks, in addition to folding and more distributed types of deformation. Predictions of brittle fracture or other types of deformation are made by comparing calculated stresses from a tectonic model to some criterion for rock strength. Common strength criteria used in the planetary science literature for near-surface deformation include a Griffith tensile-strength criterion for intact rock, a Mohr envelope for intact basalt, and a brittle strength envelope based on Byerlee's law of rock frictional resistance. However, planetary terrains of basaltic composition consist of much more than just intact basaltic rock. The aggregate basaltic material, termed the 'rock mass,' consists of both the intact rock and the associated fracture, faults, lithologic contacts, and other discontinuous surfaces. A basaltic rock mass is the relevant material for which strength properties must be defined and calculated model stresses must be compared to in order to more accurately predict brittle deformation. For example, the various strengths of a rock mass are less than that of intact material of the same composition. This means that tectonic models which compare stresses to intact failure strengths overestimate the stresses required for fracture and so underestimate the extent and magnitude of brittle deformation predicted in these models. On the other hand, rock mass shear strength can be greater than that predicted from Byerlee's law. The concept of rock mass strength is central to many engineering design studies in which calculated stresses are used to predict brittle fracture, and this experience indicates that brittle strength envelopes which assume properties for intact rock (Griffith parabolas) or sliding along a single, continuous surface (Byerlee's law) inadequately characterize the tensile, compressive, and shear strengths of rock masses. The criterion adopted here to relate stresses to rock mass fracture is based on a Griffith-type curve for tensile normal stress and a concave downward curve for compressive normal stress. It is the only available criterion that explicitly considers the weakening effects of discontinuities within the rock mass on the stress state required for fracture. Author (revised)

MARS: NEW EVIDENCE FOR ORIGIN OF SOME VALLES MARINERIS LAYERED DEPOSITS Abstract Only
David H. Scott *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1265-1266 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The discovery of layered deposits in the walls of a deep trough in Lunae Planum has implications for the origin of similar-appearing deposits in some canyons of Valles Marineris. Although layering is visible in the competent, cliff-forming upper walls of the canyons, the dissimilarity in appearance between canyon walls and soft rounded hills of layered deposits on canyon floors, as well as their contrasting patterns of erosion, has been considered strong evidence that their modes of origin were different. Most workers agree that the wall rocks are volcanic flows derived from fissure vents and other volcanic sources in the region. However, several hypotheses have been advanced to account for the softer-appearing stratified floor deposits. Chief among them is the proposal that the floor deposits are waterlaid sediments that accumulated in large lakes within the canyons and include materials eroded from canyon walls, eolian deposits, and subaqueous volcanic eruptives. POST-METAMORPHIC BRECCIATION IN TYPE 3 ORDINARY CHONDRITES Abstract Only **c90**
E. R. D. Scott, T. J. McCoy, and K. Keil *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1267-1268 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Type 3.1-3.9 ordinary chondrites can be divided into two kinds: those in which the compositions of chondrule silicates are entirely consistent with metamorphism of type 3.0 material, and those in which the computational heterogeneity appears to be too extreme for in situ metamorphism. We present petrologic data for three LL3 chondrites of the second kind--Ngawi, ALH A77278 (both type 3.6), and Hamlet (type 3.9)--and compare these data with results for the first kind of LL3-4 chondrites. Given that chondrules form in the nebula and that metamorphic equilibration occurs in asteroids, our new data imply that Ngawi, A77278, Hamlet, and many other type 3 ordinary chondrites are post-metamorphic breccias containing materials with diverse metamorphic histories; they are not metamorphic rocks or special kinds of 'primitive breccias.' We infer also that metamorphism to type 3.1-3.9 levels produces very friable material that is easily remixed into breccias and lithified by mild shock. Thus, petrologic types and subtypes of chondrites indicate the mean metamorphic history of the ingredients, not the thermal history of the rock. The metamorphic history of individual type 1 or 2 porphyritic chondrules in type 3 breccias is best derived from olivine and pyroxene analyses and the data of McCoy et al. for unbrecciated chondrites. The new chondrule classification schemes of Sears, DeHart et al., appears to provide less information about the original state and metamorphic history of individual porphyritic chondrules and should not replace existing classification schemes. CATHODOLUMINESCENCE OBSERVATIONS OF IN SITU AQUEOUS DESTRUCTION OF CHONDRULES IN THE MURCHISON CM CHONDRITE Abstract Only **c90**
Derek W. G. Sears, Paul H. Benoit, Lu Jie, and Andrew S. R. Sears *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1269-1270 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

A low-power cathodoluminescence (CL) mosaic of a 1x2 cm section of the Murchison CM chondrite contains chondrules of two types: one contains olivines with red CL and is thought to be the equivalent of group A chondrules of Sears et.; and one without observable CL, which is probably equivalent to their group B chondrules. Both types of chondrule contain dust mantles with a characteristic uniform red CL due to very fine-grained forsterites, but the mantles of group A chondrules have a complex internal structure and are much thicker than the relatively thin rims on the group B chondrules. The variety of internal textures and the progressive integration of the objects with the surrounding matrix suggests to us that these features are large group A chondrules in the process of being destroyed by aqueous alteration. Prior to aqueous alteration, group A chondrules in CM chondrites were larger than group B chondrules, which is contrary to the situation in ordinary chondrites and were apparently destroyed more rapidly than group B chondrules by aqueous alteration. DIFFUSIVE REDISTRIBUTION OF WATER VAPOR IN THE SOLAR NEBULA REVISITED Abstract Only **c92**
William D. Sears *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1271-1272 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Stevenson and Lunine presented a model for enhancing the abundance of solid material in the region of the solar nebula at the water condensation point. This was used to provide a means to produce a much more rapid formation of Jupiter than the standard solar nebula models. However, they underestimated the drag induced sun-ward radial drift of the planetesimals of interest. Reanalysis reveals that these particles would spread over the inner solar system and might influence the formation of the asteroids. Author (revised)

LUNAR BASALT METEORITE EET 87521: PETROLOGY OF THE CLAST POPULATION Abstract Only **c90**
A. S. Semenova, M. A. Nazarov, and N. N. Kononkova *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1273-1274 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The Elephant Moraine meteorite EET 87521 was classified as a lunar mare basalt breccia which is composed mainly of VLT basalt clasts. Here we report on our petrological study of lithic clasts and monomineralic fragments in the thin sections EET 87521,54 and EET 87521,47,1, which were prepared from the meteorite. The results of the study show that EET 87521 consists mainly of Al-rich ferrobasalt clasts and olivine pyroxenite clasts. The bulk composition of the meteorite can be well modelled by the mixing of these lithic components which appear to be differentiates of the Luna 25 basalt melt. KREEP and Mg-rich gabbro components are minor constituents of EET 87521. Author (revised)

Avail: CASI HC A01/MF A06

The experimental magnetic susceptibility, the temperature-independent component of the magnetic susceptibility, the magnetization, and the Curie constant have been measured for a number of specimens of glass from the K-T boundary found at Beloc, Haiti, and the results are compared with those of similar measurements of tektites. Because the Fe(3+)/Fe(2+) ratio is needed to calculate the magnetic parameters, Moessbauer spectroscopic measurements were also made. The data were consistent with the classification of the Beloc glasses as tektites. Author (revised)

RIFTING AT DEVANA CHASMA, VENUS: STRUCTURE AND ESTIMATION OF THE EFFECTIVE THICKNESS OF THE ELASTIC LITHOSPHERE Abstract Only
D. A. Senske *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1277-1278 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

To understand the relationship between extension and sites on Venus interpreted to be associated with mantle upwelling, the characteristics of the northern part of Devana Chasma in Beta Regio are examined. The structure of this rift is compared to that of terrestrial continental rifts. To ascertain the degree to which the lithosphere at Beta might be thinned, estimates of lithospheric thickness are calculated using a plate flexure model. These values are compared to those determined for other parts of the planet. Author (revised)

VOLCANIC RISES ON VENUS: GEOLOGY, FORMATION, AND SEQUENCE OF EVOLUTION Abstract Only
D. A. Senske, E. R. Stofan, D. L. Bindschadler (California Univ., Los Angeles.), and S. E. Smrekar *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1279-1280 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Large centers of volcanism on Venus are concentrated primarily in the equatorial region of the planet and are associated with regional topographic rises. Analysis of both radar images and geophysical data suggest that these uplands are sites of mantle upwelling. Magellan radar imaging provides a globally contiguous data set from which the geology of these regions is evaluated and compared. In addition, high resolution gravity data currently

being collected provide a basis to assess the relationship between these uplands and processes in the planet's interior. Studies of the geology of the three largest volcanic highlands (Beta Regio, Atla Regio, Western Eistla Regio) show them to be distinct, having a range of volcanic and tectonic characteristics. In addition to these large areas, a number of smaller uplands are identified and are being analyzed (Bell Regio, Imdr Regio, Dione Regio (Ushas, Innini, and Hathor Montes), and Themis Regio). To understand better the mechanisms by which these volcanic rises form and evolve, we assess their geologic and geophysical characteristics.

MOLECULAR EQUILIBRIA AND CONDENSATION SEQUENCES IN CARBON RICH GASES Abstract Only **c90**
C. M. Sharp and G. J. Wasserburg (California Inst. of Tech., Pasadena.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1281-1282 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Chemical equilibria in stellar atmospheres have been investigated by many authors. Lattimer, Schramm, and Grossman presented calculations in both O rich and C rich environments and predicted possible presolar condensates. A recent paper by Cherchneff and Barker considered a C rich composition with PAH's included in the calculations. However, the condensation sequences of C bearing species have not been investigated in detail. In a carbon rich gas surrounding an AGB star, it is often assumed that graphite (or diamond) condenses out before TiC and SiC. However, Lattimer et al. found some conditions under which TiC condenses before graphite. We have performed molecular equilibrium calculations to establish the stability fields of C(s), TiC(s), and SiC(s) and other high temperature phases under conditions of different pressures and C/O. The preserved presolar interstellar dust grains so far discovered in meteorites are graphite, diamond, SiC, TiC, and possibly Al2O3. Author (revised)

Avail: CASI HC A01/MF A06

The K-T-aged Chicxulub Impact Structure is buried beneath the Tertiary carbonate rocks of the Northern Yucatan Platform. Consequently its morphology and structure are poorly understood. Reprocessed Bouguer (onshore) and Free Air (offshore) gravity data over Northern Yucatan reveal that Chicxulub may be a 200-km-diameter multi-ring impact basin with at least three concentric basin rings. The positions of these rings follow the square root of 2 spacing rule derived empirically from analysis of multi-ring basins on other planets indicating that these rings probably correspond to now-buried topographic basin rings. A forward model of the gravity data along a radial transect from the southwest margin of the structure indicates that the Chicxulub gravity signature is compatible with this interpretation. We estimate the basin rim diameter to be 204 +/- 16 km and the central peak ring diameter (D) is 104 +/- 6 km. Author (revised)

BASALTIC MAGMATISM ON THE MOON. A PERSPECTIVE FROM VOLCANIC PICRITIC GLASSES Abstract Only
C. K. Shearer and J. J. Papike *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1285-1286 (For primary document see N94-20636 05-91)
(Grant NAG9-497)
Avail: CASI HC A01/MF A06

It is widely accepted that basaltic magmas are products of partial fusion of peridotite within planetary mantles. As such they provide valuable insights into the structure and processes of planetary interiors. Those compositions which approach primary melt compositions provide both a clearer vision of planetary interiors and a starting point at which to understand basaltic evolution. Within the collection of lunar samples returned by the Apollo and Luna missions are homogeneous, picritic glass beads of volcanic origin. These glass beads provide a unique perspective concerning the origin of mare basalts, the characteristics of the lunar interior, and processes culminating in the early differentiation of the moon. In this presentation, we report our ion microprobe derived trace element data from all picritic glasses previously identified. We place this trace element data and literature isotopic and experimental data on the picritic glasses with the framework of mare basaltic magmatism. Author (revised)

ORIGIN OF THE APOLLO 15 VERY LOW TI GREEN GLASS. A PERSPECTIVE FROM THE COMPOSITIONAL DIVERSITY IN THE VERY LOW TI GLASSES Abstract Only **c25**
C. K. Shearer and J. J. Papike *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1287-1288 (For primary document see N94-20636 05-91)
(Grant NAG9-497)
Avail: CASI HC A01/MF A06

The very low Ti green glasses from the Apollo 15 site have intrigued scientists for over 20 years. Their primitive composition has been used to understand magmatic processes and the structure of the moon. The compositional variability observed in the Apollo 15 glass population has long been a point of debate. Initial studies did not recognize the compositional diversity in the glasses. Stolper et al. documented the major element variability and concluded it could not be produced by magmatic processes and therefore concluded that these glasses must be of impact origin. Subsequent studies confirmed a volcanic origin for the glass population and attempted to elucidate magmatic processes to account for its compositional variability. Models that have been proposed for these glasses include the following: (1) the crystallization of single or multiple phases (olivine, pyroxene, Fe metal, immiscible sulfide); (2) the incompatible behavior of Ni and Co during multiple phase crystallization at extremely low fO2; and (3) magma or source mixing. All of these models have problems. Type (1) models appear not to be consistent with recent trace element studies on the glasses; model (2) is dependent on the debatable incompatible behavior of Ni and Co, and, in models of type (3), the origin and nature of mixing models are somewhat unconstrained. This study compares the Apollo 15 green glasses with the very low Ti picritic glasses from other landing sites. Author (revised)

Avail: CASI HC A01/MF A06

Eucrite, howardite, and diogenite members of the achondrites are considered, by many, to be genetically related. Therefore, each provide a piece of the puzzle for reconstructing magmatic processes on the eucrite parent body (EPB). The relationship between eucrites and diogenites can be viewed within the context of two distinctly different models: (1) fractional crystallization; and (2) partial melting. In fractional crystallization models, eucrites and diogenites represent a complementary continuum of planetary fractional crystallization products in which the diogenites represent crystal accumulations during the crystallization of eucritic magmas at shallow to deep levels in the EPB. Alternatively, experimental studies may be interpreted as indicating eucrites represent peritectic partial melts of a primitive, chondritic EPB mantle. Within this type of model, the diogenites are also generally considered to be cumulates; however, their petrogenetic relationship to the eucrites is less clear. Sack et al. proposed that the olivine diogenites represent residua from the partial melting events that produced eucritic liquids. Initial trace element studies of orthopyroxene (OPX) are consistent with this model. However, this trace element modeling

of the olivine diogenites is nonunique. As a further test of these models, we did the following three things: (1) analyzed OPX from cumulate diogenites to compare with the olibine diogenite data; (2) improved ion microprobe analytical techniques for the analysis of elements critical to our interpretations; and (3) selected more relevant Kd's for OPX-eucritic melt. THE ROUGHNESS OF THE MARTIAN SURFACE: A SCALE DEPENDENT MODEL Abstract Only
M. K. Shepard, E. A. Guinness, and R. E. Arvidson *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1293-1294 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

In the coming decade, several lander missions to Mars are planned (e.g., MESUR Pathfinder, MESUR). One of the dangers facing planners of these missions is the rough topography observed at both Viking Lander sites. Both landing sites are ubiquitously covered with meter-scale boulders. Objects of this size pose obvious threats to soft landers, especially at Mars where the distance from Earth causes prohibitive time lags between the transmission of commands and feedback from the spacecraft. An obvious solution is to scout for a 'smooth' site prior to the landing. However, the best resolutions realizable on current and future missions (i.e., Mars Observer) are on the order of several meters. Even at this scale, boulders of 1-2 meters in size are unresolvable. Additionally, the amount of time and spacecraft resources required to search even a small area of the planet are unrealistic given other mission objectives. An alternative is to determine the 'roughness' of the surface at a subpixel scale using bidirectional reflectance observations. Much larger areas of the planet can be searched, and much of the search can easily be automated. The morphology of the martian plains observed by the Viking Landers is physically simple. The surface is covered with a layer (approximately flat lying) of aeolian sediment from which numerous outcrops of bedrock and boulders protrude. This morphology, while simple, will be difficult to characterize from orbit using traditional bidirectional reflectance models for two reasons. First, modeling the surface as facets with Gaussian or exponential slope distributions is not realistic given the morphology described above. Second, the roughness parameter is an 'average' of the roughness at scales ranging from the wavelength of light being scattered to the pixel size of the observation. Thus, there is no definite scale of roughness that can be extracted from the Hapke roughness parameter. Using the concepts of geometric and boolean models developed by several workers, we have developed a model for the bidirectional reflectance of a surface morphology comparable to that observed at the Viking Lander sites. CHRONOLOGY OF LUNAR GRANITE 12033,576: RESETTING OF Rb-Sr AND K-Ca ISOCHRONS Abstract Only
C.-Y. Shih, H. Wiesmann, D. H. Garrison, L. E. Nyquist (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.), and D. D. Bogard (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1295-1296 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Lunar granite 12033,576 is a subsample of the 'large' (approximately 1 g) felsite 12033,507 which was identified from a collection of 4-10 mm particles from the 12033 soil sampled from the north rim of Head Crater in the eastern part of Oceanus Procellarum. Discordant ages of approximately 3.6, approximately 0.8, approximately 3.9, and approximately 2.2 Ga for this lunar granite were obtained, respectively, by the K-Ca, Ar-39/Ar-40, and U-Pb zircon methods in previous studies and by the Rb-Sr method is this study. Assuming the granite crystallized approximately 3.9 Ga ago (zircon age) and was shocked by meteoritic impacts at 0.8 Ga ago (Ar-39-Ar-40 age), the intermediate apparent ages by the Rb-Sr and K-Ca methods can be interpreted as reset by diffusion of the parent and daughter nuclides. The Rb-Sr age is less resistant to resetting than the K-Ca age, but more resistant that the Ar-39/Ar-40 age. Author

THE CHONDRITE MIHONOSEKI: NEW OBSERVED FALL Abstract Only **c90**
Masako Shima, A. Okada (Okayama Univ., Japan.), and K. Nagao (Okayama Univ., Japan.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1297-1298 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

On 10 Dec. 1992, 21:00 hours Japanese standard time, a stone weighing 6.385kg, struck a two-story house in Mihonoseki-machi, Yatsuka-gun, Shimane-ken, Japan, 35 deg 34.1 min N, 133 deg 13.2 min E. Through petrographical and mineralogical examination and rare gas analysis, the meteorite was classified as an L6 chondrite. The preatmospheric chondrite is rather small in size (Ne-22/Ne-21 = 1.180 and extremely low Co-60 activity), and shocked features are not distinct. Cosmic-ray exposure ages obtained from He-3, Ne-21, and Ar-38 are 61 m.y., and K-40/Ar-40 age is 4.41 b.y. Measurements of cosmogenic radioactive nuclides and chemical analyses are now proceeding. The Clementine Mission, a joint project of the Strategic Defense Initiative Organization (SDIO) and NASA, has been planned primarily to test and demonstrate a suite of lightweight sensors and other lightweight spacecraft components under extended exposure to the space environment. Although the primary objective of the mission is to space-qualify sensors for Department of Defense applications, it was recognized in 1990 that such a mission might also be designed to acquire scientific observations of the Moon and of Apollo asteroid (1620) Geographos. This possibility was explored jointly by SDIO and NASA, including representatives from NASA's Discovery Program Science Working Group, in early 1991. Besides the direct return of scientific information, one of the benefits envisioned from a joint venture was the development of lightweight components for possible future use in NASA's Discovery-class spacecraft. In Jan. 1992, SDIO informed NASA of its intent to fly a 'Deep Space Program Science Experiment,' now popularly called Clementine; NASA then formed an advisory science working group to assist in the early development of the mission. The Clementine spacecraft is being assembled at the Naval Research Laboratory, which is also in charge of the overall mission design and mission operations. Support for mission design is being provided by GSFC and by JPL. NASA's Deep Space Network will be utilized in tracking and communicating with the spacecraft. Following a recommendation of the COMPLEX committee of the Space Science Board, NASA will issue an NRA and appoint a formal science team in early 1993. Clementine is a 3-axis stabilized, 200 kg (dry weight) spacecraft that will be launched on a refurbished Titan-2G. One of the goals has been to build two spacecraft, including the sensors,

for $100M. Total time elapsed from the decision to proceed to the launch will be two years. Author (revised)

RESEARCH PROGRAM ON THE MANSON IMPACT STRUCTURE, IOWA Abstract Only c46
E. M. Shoemaker, D. J. Roddy, and R. R. Anderson (Geological Survey, Iowa City, IA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1301-1302 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

At or near the end of the Cretaceous, at least two large impact events occurred in the western hemisphere. One impact formed the 180-km diameter Chicxulub crater on the northern tip of the Yucatan peninsula. Another formed the 35-km diameter Manson structure in western Iowa. Several lines of evidence, including the chemical and isotopic composition of glass found in the K/T boundary layer at sites in the Gulf of Mexico and Caribbean region, the regional variation in thickness and the size of spherules in the K/T boundary layer, and indications at and near the boundary of disturbance and deposition of beds by giant waves in the Gulf of Mexico, point to Chicxulub as a major source of K/T boundary material, including a lower layer of clay at K/T boundary sites in western North America. The size, abundance, and mineral and lithic composition of shocked grains from an upper K/T boundary layer found at western North American sites, on the other hand, point to Manson as a possible source crater. More than one impact seems to be indicated by the K/T boundary stratigraphy in western North America, and present constraints on the age of the Manson structure suggest that it, as well as Chicxulub, may be a K/T boundary crater. Multiple craters produced over a relatively short interval of time are much more likely to have been formed by impact of comets rather than by impact of asteroids. Among likely mechanisms that could have produced multiple craters at or near the time of the K/T boundary are as follows: (1) splitting of a comet shortly before impact with Earth (impacts may have been spaced over about an hour), (2) fragmentation of a very large, Sun-grazing, periodic comet to form a compact stream of comets that intercepted the Earth's orbit (impacts may have been spread over about a century), and (3) perturbation of the Oort comet cloud by a passing massive object to form a comet shower in the inner solar system (impacts may have been spread over about a million years). Only in the first two cases are the impacts likely to have been close enough in time to contribute to the observed K/T boundary layers. All mechanisms could have produced many more than two craters. PETROGRAPHY OF SHOCK FEATURES IN THE 1953 MANSON 2-A DRILL CORE Abstract Only c46
N. M. Short and D. P. Gold *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1303-1304 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Drilling of Nx core in late 1953 into an anomalous zone of disturbed rocks northwest of Manson, Iowa disclosed presence of extensive breccias including crystalline rocks brought to the surface from depths of 4 km or more. Hole 2-A penetrated breccias dominated by leucocratic igneous and metamorphic lithologies, later interpreted to be part of a general ringed peak complex within a 35 km wide impact structure produced about 65 Ma ago. Proof of this origin was given in 1966 by NMS through recognition of shock metamorphic features in 2-A materials during a cursory examination of samples provided by R.A. Hoppin, University of Iowa. A detailed study of this material now underway has revealed that most breccia clasts in 2-A show abundant and varied evidence of shock damage, including extensive planar deformation features (PDF) in quartz, K-feldspar, plagioclase, and a pyroxene and varying degrees of isotropization and incipient melting in feldspars. FE-60 AND THE EVOLUTION OF EUCRITES Abstract Only c90
A. Shukolyukov and G. W. Lugmair *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1305-1306 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

We have recently presented evidence for the existence of live Fe-60 in the early solar system. This evidence comes from observations of 2.4 to 50 epsilon unit (1 part in 10(exp 4)) relative excesses of Ni-60 measured in samples from the eucrite Chervony Kut (CK). These isotopic excesses have been produced by the decay of the short-lived radionuclide Fe-60 (T(sub 1/2) = 1.5 Ma). Because CK originates from a planetesimal which was totally molten and its high Fe/Ni ratio is due to a planet-wide Fe-Ni fractionation during metal-silicate segregation, the presence of the Fe-60 decay product indicates the large scale abundance of Fe-60 in the early solar system and its presence during differentiation of this planetesimal. The observed variable Ni-60 excesses in different bulk samples and mineral separates from CK can only be understood if some Fe-60 was still alive at the time when basaltic magma had solidified on the eucrite parent body. The lack of a correlation between Ni-60 and the respective Fe/Ni ratios in different mineral fractions from CK indicates a metamorphic remobilization of Ni after essentially all Fe-60 has decayed. However, Ni-60 from three bulk samples from different locations within the meteorite appears to correlate reasonably well with the respective Fe/Ni ratios. If we regard this correlation as an isochron then its slope yields a Fe-60/Fe-56 ratio f (3.9 +/- 0.6) x 10(exp -9) and an initial Ni-60 of 3.2 plus or minus 0.9 epsilon units at the time of crystallization of CK. Estimates based on these values and a approximately 10 Ma time interval between CK solidification and formation of the earliest condensates in the solar system followed by rapid accretion of planetary bodies indicate that the decay of Fe-60 could produce sufficient heat to melt these planetesimals. If Al-26 was present on a planetary scale as Fe-60 and at abundances close to values observed in Allende inclusions then melting of small early formed planets is inevitable. As an attempt to further explore the Fe-60/Ni-60 isotope system as an early solar system chronometer we studied another noncumulate eucrite, Juvinas (JUV) (sample USNM 1051), which belongs to the same subgroup as CK. GEOID, TOPOGRAPHY, AND CONVECTION-DRIVEN CRUSTAL DEFORMATION ON VENUS Abstract Only
Mark Simons, Bradford H. Hager, and Sean C. Solomon (Carnegie Institution of Washington, DC.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1307-1308 (For primary document see N94-20636 05-91)

High-resolution Magellan images and altimetry of Venus reveal a wide range of styles and scales of surface deformation that cannot readily be explained within the classical terrestrial plate tectonic paradigm. The high correlation of long-wavelength topography and gravity and the large apparent depths of compensation suggest that Venus lacks an upper-mantle low-viscosity zone. A key difference between Earth and Venus may be the degree of coupling between the convecting mantle and the overlying lithosphere. Mantle flow should then have recognizable signatures in the relationships between the observed surface topography, crustal deformation, and the gravity field. Therefore, comparison of model results with observational data can help to constrain such parameters as crustal and thermal boundary layer thicknesses as well as the character of mantle flow below different Venusian features. We explore in this paper the effects of this coupling by means of a finite element modelling technique. Author (revised)

PETROGRAPHY AND ORIGIN OF REFRACTORY INCLUSIONS FROM THE MURRAY AND MURCHISON C2 CHONDRITES Abstract Only c90
S. B. Simon, L. Grossman, and A. Hsu (Illinois Mathematics and Science Academy, Aurora.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1309-1310 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

By freeze-thaw disaggregation, we have recovered a total of 47 refractory inclusions. New discoveries include the following: a hibonite-pyroxene spherule from Murray; a CaAl4O7-bearing spherule from Murchison; and a Sc-fassaite-bearing ultrarefractory inclusion from Murchison. Freeze-thaw disaggregation, combined with density separation and hand-picking as described is a proven method for recovering rare objects from carbonaceous chondrites. This method is especially effective on C2's due to their porosity and typically results in the discovery of new types of refractory inclusions.

Because few refractory inclusions from Murray have been described, we studied this meteorite, although only a small amount of material (730 mg) was available for disaggregation. Many refractory inclusions from Murchison have been described, and we disaggregated a larger amount (approximately 18 g) of Murchison in an attempt to find new types of refractory inclusions, especially corundum-bearing ones. SCATTERING BY VENUS' SURFACE Abstract Only
R. A. Simpson, G. L. Tyler, M. J. Maurer, E. Holmann, and P. B. Wong *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1311 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

During 1992, Magellan altimetry echoes were processed to yield scattering functions sigma(sub o)(phi) over near-nadir angles phi less than or equal to 10 deg from some 2000 Venus orbits. SAR image strips acquired simultaneously at oblique angles were also reduced to give scattering functions but over a few deg of incidence angle in the range 15 less than or equal to phi less than or equal to 45 deg. By sorting, the altimetry and SAR results can be combined to give composite scattering functions for much of Venus' surface. The data in hand should allow definition of such composite functions for 70-80 percent of Venus at resolutions of 20 km--approximately one million separate functions. Author (revised)

VENUS GRAVITY: NEW MAGELLAN LOW ALTITUDE DATA Abstract Only
W. L. Sjogren, Konopliv. A. S., N. Borderies, M. Batchelder (Telos Aerospace Systems, CA.), J. Heirath (Sterling Software, Inc., Palo Alto, CA.), and R. N. Wimberly (Sterling Software, Inc., Palo Alto, CA.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1313-1314 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Acquisition of a new high quality gravity data set has begun. The data set presently covers one third of the Venusian longitude. Better spatial resolution is obtained from a 60th degree and order spherical harmonic solution. Plans for aerobraking in May 1993 into a near circular orbit will provide excellent data for higher latitude regions. Author (revised)

SIZE DISTRIBUTIONS AND AERODYNAMIC EQUIVALENCE OF METAL CHONDRULES AND SILICATE CHONDRULES IN ACFER 059 Abstract Only **c90**
William R. Skinner and James M. Leenhouts (Arizona Univ., Tucson.) *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1315-1316 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

The CR2 chondrite Acfer 059 is unusual in that the original droplet shapes of metal chondrules are well preserved. We determined separate size distributions for metal chondrules and silicate chondrules; the two types are well sorted and have similar size distributions about their respective mean diameters of 0.74 mm and 1.44 mm. These mean values are aerodynamically equivalent for the contrasting densities, as shown by calculated terminal settling velocities in a model solar nebula. Aerodynamic equivalence and similarity of size distributions suggest that metal and silicate fractions experienced the same sorting process before they were accreted onto the parent body. These characteristics, together with depletion of iron in Acfer 059 and essentially all other chondrites relative to primitive CI compositions, strongly suggest that sorting in the solar nebula involved a radial aerodynamic component and that sorting and siderophile depletion in chondrites are closely related. GMM-1: A 50 DEGREE AND ORDER GRAVITATIONAL FIELD MODEL FOR MARS Abstract Only
D. E. Smith, F. J. Lerch, R. S. Nerem, M. T. Zuber (Johns Hopkins Univ., Baltimore, MD.), G. B. Patel (Hughes STX, Inc., Lanham, MD.), S. K. Fricke (RMS Technologies, Inc., Landover, MD.), and F. G. Lemoine *In* Lunar and Planetary Inst., Twenty-Fourth Lunar and Planetary Science Conference. Part 3: N-Z 1993 p 1317-1318 (For primary document see N94-20636 05-91)
Avail: CASI HC A01/MF A06

Knowledge of the gravitational field, in combination with surface topography, provides one of the principal means of inferring the internal structure of a planetary body. The highest resolution gravitational field for Mars published thus far was derived from Doppler tracking data from the Mariner 9 and Viking 1 and 2 spacecraft and is complete to degree and order 18 corresponding to a half wavelength resolution of approximately 600 km. This field, which is characterized by a spatial resolution that is slightly better than that of the highest resolution (16x16) topographic model, has been utilized extensively in analyses of the state of stress and isostatic compensation of the Martian lithosphere. However, the resolution and quality of current gravity and topographic fields are such that the origin and evolution of even the major physiographic features on Mars, such as the hemispheric dichotomy and Tharsis rise, are not well understood. We have re-analyzed the Viking and Mariner data sets and have derived a new gravitational field, which we designated GMM-1 (Goddard Mars Model-1). This model is complete to spherical harmonic degree and order 50 with a corresponding (half wavelength) spatial resolution of 200-300 km where the data permit. In contrast to previous models, GMM-1 was solved to as high degree and order as necessary to nearly exhaust the attenuated gravitational signal contained in the tracking data. Author (revised)
